Introduction

In geochemical reaction modeling, as the name suggests, you construct numerical simulations of reactions that might occur in the geochemical environment. You might, for example, wish to model the consequences of a specific fluid reacting with a certain set of minerals. For a detailed description of such modeling, as well as a large number of fully worked examples, please see the *Geochemical and Biogeochemical Reaction Modeling* text by Craig M. Bethke, available from Cambridge University Press.

In The Geochemist's Workbench, you use **React** to trace reaction models and **Gtplot** to render graphically the results of **React** simulations.

1.1 React program

React is a flexible program that models equilibrium states and geochemical processes in systems that contain an aqueous fluid. Like **SpecE8**, **React** can calculate the equilibrium distribution of aqueous species in a fluid, a fluid's saturation state with respect to minerals and solid solutions, and the fugacity and partial pressure of gases dissolved in a fluid.

The program can also trace the evolution of a system as it undergoes reversible or irreversible reaction in an open or closed system, either at a given temperature or polythermally. **React** can integrate kinetic rate laws and simulate the fractionation of stable isotopes in a reacting system.

React is, in fact, an extension of program **SpecE8**, which is described in the **GWB Essentials Guide**, in the section **Using SpecE8**. You should, therefore, become familiar with **SpecE8** and its documentation before beginning to work with **React**.

The next three sections of this manual introduce the program, show how to construct reaction paths, show how to trace kinetic reaction paths, and give details on constructing custom rate laws.

1.2 Gtplot program

Gtplot is used to render the results of **React** simulations graphically. The program is driven interactively, using the mouse, and offers the capability of displaying reaction models in a variety of ways. The **Using Gtplot** section of this manual shows how to use this program.

1.3 Phase2 program

Phase2 is a program for calculating phase and predominance diagrams of virtually any type. The program works by tracing a series of stacked reaction paths across the diagram. Each traverse is conceptually identical to a **React** simulation. As such, **Phase2** can account not only for multicomponent chemical equilibrium, but reaction kinetics, external buffers, sorption and surface complexation, stable isotope fractionation, and, in fact, any of **React**'s many capabilities.

A **Phase2** diagram differs from a simple diagram of the type constructed by **Act2** and **Tact** in that each point in the diagram represents the complete solution to the equations describing the system's distribution of mass. If you were to use **Phase2** to calculate an Eh-pH diagram, for example, you would find that, unlike the result from **Act2**, the boundary lines are curved, rather than linear. Because of the calculation's completeness, some **Phase2** diagrams differ qualitatively from their **Act2** counterparts. For this reason, the diagrams are sometimes referred to as "true" Eh-pH or "true" activity diagrams.

Phase2 diagrams, furthermore, can be plotted over a wide range of variable choices, and in a variety of ways. To learn more about **Phase2** and its abilities, visit the **Using Phase2** section of this manual.

1.4 P2plot program

P2plot is used to render the results of **Phase2** simulations graphically. The program is similar to **Gtplot** and **Xtplot**, which are described in the **Using Gtplot** section of this manual and the **Using Xtplot** section of **GWB Reactive Transport Modeling Guide**, respectively. Specifically, **P2plot** can diagram phase assemblages, predominant phases and species, gas pressures, isotope compositions, and even cross sections through the diagram. The **Using P2plot** section of this manual shows how to use this program.

1.5 Example input files

Subsequent chapters of this manual contain examples of applying **React** to trace reaction models in various configurations, and using **Phase2** to create diagrams of differing types. An input file corresponding to each example is available in the GWB installation directory (e.g., "\Program Files\GWB") under the subdirectory "Script".

The example files for program **React** are:

- "Feldspar.rea"
- "Dolomite.rea"
- "IonEx.rea"
- "Evaporate.rea"
- "Flush.rea"
- "Steam.rea"
- "Pyrite.rea"
- "Degas.rea"
- "Uranium.rea"
- "Surface.rea"
- "Goethite_Se.rea",
 "Goethite_NaCl.rea",
 "Goethite_NaClO4.rea"
- "Goethite_Cu.rea", "Goethite_P.rea"
- "Flash.rea"
- "Isotope.rea"
- "Kinetic.rea"
- "Albite.rea"
- "Nonlinear.rea"
- "Assosciation.rea"
- "Desorption.rea"
- "GasTransfer.rea"
- "Redox.rea"
- "Catalysis.rea"
- "Enzyme.rea"
- "Microbes.rea"
- "Script.rea"

- Kinetics of sorption
- Kinetics of degassing
- Kinetics of redox reactions
- Catalysis on mineral surfaces
- Enzymes and biotransformations
- Microbial metabolism and growth
- Control script (see **Control Scripts** in the **GWB Reference Manual**)

The example **Phase2** files are:

- "CuSH2O.ph2"
- " Speciation diagram " Mineral solubility
- "AlSolubility.ph2" "O2Solubility.ph2"
- Gas solubility
- "CO2_frac.ph2"
- "ZnSorption.ph2"
- "Promoting.ph2"
- Isotope fractionation
- Surface complexation
- Kinetic diagram

Getting Started with React

React, as described in the **Introduction** to this guide, is a program designed for modeling irreversible reaction process in geochemical systems. This section provides an introduction to the program, and subsequent sections give details on constructing various types of reaction paths, accounting for kinetic reactions, and constructing custom rate laws.

2.1 Conceptual model

A **React** model calculation has two main components: the initial system and the process that alters it.

React begins a simulation by calculating the system's initial equilibrium state. The program then changes the system by adding (or removing) reactants to vary the system's composition, changing the temperature, or varying the fugacity of gases in an external buffer. This process is the reaction path; a representation is shown below.

In the figure, a system containing an aqueous fluid and perhaps minerals remains in equilibrium as its composition, temperature, or both change over the course of a reaction path. Changes in composition can reflect explicit transfer of reactants into and out of the system, and the transfer implicit in buffering gas fugacities and species activities.

Progress along the reaction path is measured arbitrarily in terms of a reaction progress variable ξ , which varies from 0 initially to 1 at the end of the path. Variable ξ , which is dimensionless, has meaning only in terms of how the user has defined the reaction path.

2.2 Example calculation

The input file "Feldspar.rea" equilibrates a hypothetical water sample at 25°C and then reacts it with potassium feldspar. Double-click the file, which can be found in the "Scripts" subfolder of the GWB installation directory, to launch **React**. The **Basis** pane

ζ React : Feldspar.rea						_		Х
<u>File E</u> dit Run Config <u>V</u> iew <u>H</u> e	lp					 		
Basis Reactants Med	ium	Command	Results			 		
constraints on initial system

						_		
<								>

describes the composition of the hypothetical water.

Move to the Reactants pane

to see how potassium feldspar is reacted into the fluid. The following commands

```
Na+ = 5 mg/kg
K+ = 1 mg/kg
Ca++ = 15 mg/kg
Mg++ = 3 mg/kg
Al+++ = 1 ug/kg
SiO2(aq) = 3 mg/kg
Cl- = 4 mg/kg
SO4-- = 8 mg/kg
HCO3- = 50 mg/kg
pH = 5
react 400 mg of K-feldspar
```

configure the same reaction path.

When setting the concentration or activity of species, the mass of minerals, or the fugacity or partial pressure of gases in the **Basis** pane, it is important to avoid 0 (zero) values, as these will prevent the GWB programs from solving for the distribution of mass. Where the concentration of a particular component is negligible, set a small positive value. Log values, such as log activity, pH, pe, or Eh, however, can be set to 0.

Press the **Run** button on the **Results** pane to trace the reaction path.

ζ React : Fel	dspar.rea				_	\times

						 -
Follow Out	put					
Dura	View Resul	Dist David				
Run	view Result	ts Plot Resul	ts			

You can alternatively select **Run** \rightarrow **Go** from the menubar or type go in the **Command** pane.

React produces as output a dataset "React_output.txt" (**View Results**) that shows calculation results in tabular form, and a dataset "React_plot.gtp" (**Plot Results**) that passes more complete information to the graphics program **Gtplot** (see **Using Gtplot**). **Act2** and **Tact** can project traces of reaction paths on stability diagrams, and **P2plot** on its 2D diagrams, in which case they also read the "React_plot.gtp" dataset.

The mineralogic results of the reaction, as plotted by **Gtplot**,

show the results of reacting potassium feldspar into a dilute water at 25°C. The reaction continues until, when about 330 mg of reactant have been added, the fluid reaches equilibrium with K-feldspar.

2.3 Initial system

The initial system in a **React** simulation is an equilibrium model of the aqueous fluid and any coexisting minerals, solid solution end members, and gases. You constrain the initial system precisely as you would set up an equilibrium model with **SpecE8** (see **Equilibrium models** under **Using SpecE8** in the *GWB Essentials Guide*).

The two programs differ in that **React**, by default, forces electrical charge balance on the system, whereas **SpecE8** does not. To achieve identical output, you should either set **SpecE8** to charge balance on the same basis entry as **React**, or disable charge balancing in **React**. Specify a basis entry to charge balance on by selecting "Balance species" under the entry's unit pulldown on the **Basis** pane,

Basis Re	actants	Medium	Command	Results

_ time start	0.0	uuy			J			mg ug ng wt fraction wt% eq	>	
_ time start	0.0				a y			mg ug ng wt fraction wt% eq meq	> >	
_ time start	0.0				a y			mg ug ng wt fraction wt% eq meq ueq	> > > >	
_ time start	0.0				a y			mg ug ng wt fraction wt% eq meq ueq neq	> > > >	
_ time start	0.0				a y			mg ug ng wt fraction wt% eq meq ueq neq activity	> > > > >	

and disable charge balance by deselecting "Balance species" from the pulldown. You can also disable charge balance from any charged species' pulldown, not just the current balancing ion, by selecting "Do not balance" from the pulldown. Since **React**, by default, uses Cl⁻ as the charge balancing ion, this option is especially useful for systems that don't include any Cl⁻.

The programs also differ in that **React**, having figured the distribution of species in the initial system, will by default attempt to find the system's true equilibrium state by allowing any supersaturated minerals or solid solutions to precipitate. If you do not want the program to take this step, click on **Config > Options...**

S Options X
options Kd precipitation sorbate gas pressure model default
density method Batzle-Wang ▼ use NaCl fluid of same ● TDS ◯ chlorinity
log K span □ extrapolate □ span min
OK Apply Cancel Reset

and uncheck the box labeled "precipitation".

If you run **React** on an initial system containing supersaturated minerals, and do not disable the precipitation option, you should expect two blocks of output in "React_output.txt" (**File** \rightarrow **View** \rightarrow **React_output.txt**). Each block contains calculation results, including the concentration of a number of aqueous species, the saturation state of various minerals and solid solutions, the fugacity and partial pressure of gases, and the system's bulk composition.

If, for example, you run **React** on the seawater example provided for **SpecE8** (the input is given in **Equilibrium models** under **Using SpecE8** in the *GWB Essentials Guide*), the output dataset will contain two blocks. The top block gives results of the first calculation performed by **React**. The calculation predicts that seawater is supersaturated with respect to a number of minerals, including antigorite and dolomite. The results in this block, then, represent seawater in a metastable state. The fluid's bulk composition (but not the concentrations of free species), as well as the CO₂ and O₂ fugacity, reflect the input constraints.

The program continues to calculate the equilibrium state that seawater, according to the model, would reach if supersaturated minerals were allowed to precipitate. The second block in the dataset gives results of this calculation, which predicts that, at equilibrium, dolomite and quartz coexist with seawater. Precipitating these minerals alters the fluid composition so that the pH and CO_2 fugacity reported in the second block differ from the original values.

Finding the true equilibrium state of seawater is a somewhat academic pursuit because mineral precipitation from seawater is too slow to observe. You can tell **React** to not allow any new minerals or solid solutions to form by turning off the "precipitation" option on the **Config → Options...** dialog, or with the precip off command. In this case, only one block of results would appear in "React_output.txt".

2.4 Redox disequilibrium

React, like the other GWB programs, can account for the redox disequilibrium commonly observed in natural waters. You control the extent to which **React** honors redox equilibrium when calculating a chemical model by interactively enabling and disabling redox coupling reactions.

See **Redox couples** in the **Configuring the programs** section of the *GWB Essentials Guide* for information about decoupling redox reactions, and **Redox disequilibrium** in the **Using SpecE8** section of that guide for specific instructions on constructing disequilibrium models in **React**.

2.5 Activity coefficients

Like **SpecE8**, **React** employs various methods for calculating activity coefficients, including:

- The "B-dot" equation, an extended form of the Debye-Hückel equation
- The Specific ion Interaction Theory (SIT method)
- The Harvie-Møller-Weare implementation of the "Pitzer equations"
- The activity models implemented in the MINTEQ, PHREEQC, PHRQPITZ, and WATEQ4F geochemical modeling programs, as well as the Davies equation

For more information, see **Activity coefficients** in the **Using SpecE8** section of the **GWB Essentials Guide.**

2.6 Solid solutions

React, like the other GWB programs, can account for binary solid solutions (See **Solid solutions** in the **Configuring the programs** section of the *GWB Essentials Guide*). Like **SpecE8**, it can consider continuous and discrete modes, and in either case it can treat solid solutions as ideal or calculate activity coefficients according to various models:

- Site-mixing
- Guggenheim
- Regular
- Cubic Maclaurin
- Third-order Maclaurin

For more information on including solid solutions in **React**, see **Solid solutions** in the **Using SpecE8** section of the *GWB Essentials Guide*.

2.7 Sorption onto mineral surfaces

React can model the sorption of species from solution onto mineral surfaces, according to several methods (see **Sorption onto mineral surfaces** in the **Configuring the programs** section of the **GWB Essentials Guide**). The methods include

- Two-layer surface complexation
- Triple-layer surface complexation
- CD-MUSIC
- Ion exchange
- Distribution coefficients (K_d)
- Freundlich isotherms
- Langmuir isotherms

For more information on applying these methods within **React** simulations, see **Sorption onto mineral surfaces** in the **Using SpecE8** section of the *GWB Essentials Guide*.

2.8 Settable variables

React allows you to alter the values of certain variables carried in the calculation. **Table 2.1** lists these variables and their units and default values. To change a variable, type the new value on the **Basis** or **Medium** pane or in the dialog boxes under **Config**, or enter as a command the variable name followed by the new value. Examples:

```
itmax = 1000
delxi = 5/100
```

The value given must be in the units carried internally by the program, as listed in **Table 2.1**. To restore a variable to its default value, enter a blank field in the dialog box, or on the **Command** pane type its name without a value or followed by a ?:

delxi delxi = ?

Current values of the variables can be viewed at any time on the relevant dialog box, or using the command show variables.

Table 2.1	Settable variable	s, their unit	s and defa	ault values
Pane or Dialog	Variable	Default	Unit	Description
Basis	density	not set	g/cm³	Density of initial fluid.
	TDS	not set	mg/kg	Total dissolved solids, initial fluid.
Medium	cpw	1	cal/g°C	Fluid (water) heat capacity (polythermal mixing).
	cpr	.2	cal/g°C	Mineral (rock) heat capacity (polythermal mixing).
	inert	0	cm ³	Unreactive volume (porosity calculation).
Iteration	epsilon	5 x 10 ⁻¹¹	-	Convergence criterion.
	itmax	999	-	Allowed number of iterations.
	nswap	30	-	Allowed number of basis changes to find stable mineral assemblage, reaction step.
	pitz_dgamma	0.1	-	For virial activity coefs., maximum fractional change per iteration.
	pitz_precon	10	-	For virial activity coefs., maximum number of pre- conditioning steps.
	pitz_relax	0.5	_	For virial activity coefs.,

				relaxation factor during iteration.
	simax	3	molal	Maximum stoichiometric ionic strength used to calculate water activity (Debye-Hückel model).
	timax	3	molal	Maximum true ionic strength used to calculate activity coefficients (Debye- Hückel model).
Stepping	cpu_max	not set	S	Amount of computing time a simulation may take.
	delQ	.1	-	$\Delta Q/Q$ allowed over a step, for kinetic reactions.
	delxi	.01	-	Step size in reaction progress, log/linear stepping.
	dx_init	not set	-	Initial step size in reaction progress.
	step_increase	1.5	-	Maximum proportional increase in step size.
	step_max	not set	-	Number of reaction steps the program may take to trace a simulation.
	theta	.6	-	Time weighting for tracing kinetic rate laws.
Output	dxplot	.005	-	Interval in reaction progress between plot points.
	dxprint	.1	-	Interval between printing results.

2.9 Controlling the printout

React lets you control the amount of detail presented in the calculation results written to "React_output.txt". The dataset is known commonly as the "printout", although it need never be printed. The printout can contain information about (1) the concentration and activity of dissolved species, (2) the saturation indices of various minerals and solid solutions, (3) gas fugacity and partial pressure, (4) surface complexes, and (5) the elemental composition of the fluid, mobile colloids, stagnant zone, and bulk system, (6) those compositions expressed in terms of either the current or original basis, and (7) the diffusion profile within the stagnant zone. The printout can also contain a list of the chemical reactions considered in the calculation.

You can specify that any of these lists be excluded from the printout or included in a short or long format. The program, by default, produces lists of dissolved species and mineral saturation states in a short format, which includes only species present in concentrations greater than 10^{-8} molal and minerals with saturation indices greater than -3. The fugacity and partial pressure of each gas appears in the printout, as does composition in terms of elements and the original basis.

To vary the printout, the user can set each aspect in **Table 2.2** to "none", "short", or "long" on the **Config → Output...** dialog

ξ Output		×

2.10 React command line

You can start **React** by clicking the icon on the GWB dashboard, opening a ".rea" file, or entering the command react.exe from the Windows "Command Prompt".

When you start **React** from the command line (as opposed to clicking on the icon), you can specify a number of arguments. For example, the command

```
react -i my_script -d my_thermo.tdat
```

causes **React** to read input commands from a file "my_script", and to use "my_thermo.tdat" as the thermodynamic database.

-cd	Change the working directory to the directory containing the input script specified with the –i option.
-nocd	Do not change the working directory.
<input_script> -i <input_script></input_script></input_script>	Set a file from which to read input commands.
-gtd <gtdata_dir></gtdata_dir>	Set directory to search for thermodynamic datasets.
-cond <cond_data></cond_data>	Set the dataset for calculating electrical conductivity.
-d <thermo_data></thermo_data>	Set the thermodynamic dataset.
-iso <isotope_data></isotope_data>	Set the dataset of isotope fractionation factors.
-s <surface_data></surface_data>	Set a dataset of surface sorption reactions.

The following options are available from the command line:

Tracing Reaction Paths

React can trace several types of reaction paths, including

- Titration paths, in which a reactant is gradually added to a geochemical system.
- Polythermal paths, in which temperature varies.
- Sliding paths, in which a species activity or gas fugacity varies.
- Kinetic paths, in which the rate of reaction progress is described by a kinetic rate law.

These types of paths can be combined into a single **React** simulation.

This section of the guide describes how to construct the first three types of reaction paths, and the following two sections give details on constructing kinetic reaction paths.

3.1 Titration paths

In simple reaction paths, one or more reactants are gradually added to (or removed from) the system over the course of the calculation. Such paths are sometimes called "titration paths" because the program repeatedly adds a small aliquot of reactant and then recalculates the system's equilibrium state as it steps forward in reaction progress. Other methods of varying the system composition, such as **buffered paths**, **sliding activity and fugacity paths**, and **kinetic paths**, are discussed in later sections of this manual.

In the following example, the program simulates reaction of an alkaline industrial waste that has been pumped into an injection well with a dolomite formation receiving the waste. Double-click on file "Dolomite.rea" (the file can be found in the "Scripts" folder within the GWB installation directory), and when **React** opens, look at the **Basis** pane,

🗧 React : Dolomite.rea ile <u>E</u> dit Run Confi					- 0	×
Basis Reacta	ants Medium	Command	Results			
- constraints on initial sy	/stem					_
	H2O		1.0	▼ free kg ▼	solvent

	нсоз- 😫		1.0	▼ mg/kg ▼		
	Mg++		1.0	▼ mg/kg ▼		
	Na+ 🛱			▼ mg/kg ▼	charge balance	
	temperature		50.0	▼ c ▼		
			+ advanced			
add delete						
time start 0.0) 🔻 day 🔻	end 1.0	▼ day ▼			
						>

which contains the composition of the alkaline waste. You don't need to constrain the concentration of Na⁺ because it's selected as the charge balancing ion.

If the fluid composition wasn't already set, you would do so by clicking the add button to add entries to the basis, then select units from the pulldown for each entry and constrain their values. To set Na⁺ as the charge balancing ion, select the "Balance species" option from its unit pulldown.

Move to the **Reactants** pane.

Keact : Dolomite.rea	-	×
<u>Eile E</u> dit Run Config <u>V</u> iew <u>H</u> elp		
Basis Reactants Medium Command Results		
reactants and kinetic reactions		
+ React 50 cm3 of Dolomite		
add delete		
reactants times 1.0		
<.		>

The input sets up the irreversible reaction of dolomite into the NaOH-NaCl waste. If the titration path isn't already set up, you can do so by going to \blacksquare **dd** \rightarrow **Simple** \rightarrow **Mineral...** \rightarrow **Dolomite** and specifying the amount to react.

Tracing Reaction Paths 21

You could also have used the commands

```
T = 50

pH = 13

Cl- = 3 molal

Ca++ = 1 mg/kg

HCO3- = 1 mg/kg

Mg++ = 1 mg/kg

balance on Na+

react 50 cm3 Dolomite

go
```

The initial commands correspond to the settings on the **Basis** pane, while the final step matches the input to the **Reactants** pane.

In the example, the program reacts 50 cm³ of dolomite over the reaction path. If the program takes 100 reaction steps of $\Delta \boldsymbol{\xi} = .01$, then a half cm³ of dolomite is added to the system at each step. As can be seen in the calculation results,

dolomite reacts with the fluid to form calcite and brucite until the fluid becomes saturated. Reaction stops at this point, so that any dolomite further added to the system simply accumulates.

Aqueous species and gases, as well as minerals, solid solution end members, and fictive oxide components, may serve as reactants in titration paths. Reactant quantities can be set in a variety of units, listed in **Table 3.1**.

```
Table 3.1
           Units for specifying reaction rates

 volume%, vol. fract.
By absolute rate (append):
```

/s, /min, /hr, /day, /yr, /m.y.

As many reactants as desired can be specified: click \rightarrow **Simple** on the **Reactants** pane, or use a react command for each. If multiple reactants are set, the program adds each to the system at a rate in proportion to its total mass.

The role of reactants is to change the system's composition. For this reason, only the reactant's composition is important. Quartz, for example, could be replaced as a reactant by the silica polymorph tridymite, $SiO_2(aq)$, or even the fictive oxide SiO_2 without affecting the calculation results.

reactants times 1.0		`

React provides a convenient method to take the fluid composition resulting from an equilibrium model and use it as a reactant, without reentering the reactant's composition as done here (see **Picking up the results of a run**, later in this section).

React normally adds reactants at rates that remain constant over the path, but a cutoff value may be set on the **Reactants** pane (click + next to the reactant in question), or with the react command. The input

- reactants and kir	netic reactions			
- React Qua	artz	0.5	•	g 🔻
cutoff	[•	g
- React Albi	ite	1.0	•	g *
cutoff	[0.5	•	g

or the equivalent steps

```
(define an initial system)
react 1/2 g Quartz
react 1 g Albite cutoff = 1/2
```

cause a half gram of quartz and albite to be reacted. The program adds quartz continuously over the path, whereas it reacts albite twice as quickly as quartz over the first half of the path and not at all over the second.

A final feature of **React** is the "dump" option. When this option is set, the program removes any minerals present in the initial system before beginning the reaction path. The option is useful for simulating separation of a fluid from a rock with which it was in equilibrium, before beginning a path. For example, you may want to separate a geothermal fluid from the reservoir rocks before modeling how the fluid could react to form scale. Set the option from the **Config → Stepping...** dialog or by typing dump.

ξ Stepp	oing		×
delQ	0.1	dx_init	
delxi	0.01	step_increase	1.5
theta	0.6	progress	banner 🔻

start	t date 2/ 7/20	18	
start	t time 2:15:19	PM	
OK	Apply	Cancel	Reset

Unchecking "dump" or using the dump off command turns off the option.

3.2 Flow-through model

React features a "flow-through" model in which minerals and end members are prevented from dissolving once they precipitate. The model is useful for modeling reaction of a packet of fluid as it migrates through an aquifer. Once minerals form, they are isolated from the packet so that they cannot back-react with the fluid should they become undersaturated farther along the flow path. Implement the flow-through model from the **Config → Stepping...** dialog, or by typing flow-through.

special c	onfigurations – hrough	dump	
flush		end-dump	
flash	off		

To turn the model off, uncheck "flow-through" or type flow-through off.

The flow-through model can be applied to a variety of problems in which minerals are unlikely, for physical or chemical reasons, to dissolve once they form. To simulate evaporation of seawater, for example, the model provides a way to account for the settling of minerals to the sea floor. Double-click the "Evaporate.rea" input file to launch **React**.

The Harvie-Møller-Weare activity model is specified to account for the high ionic strength of evaporated seawater. If not already loaded, you could do so by going to **File** \rightarrow **Open** \rightarrow **Thermo Data...** and selecting "thermo_hmw.tdat". You can view the contents of the dataset by going to **File** \rightarrow **View** \rightarrow **.\thermo_hmw.tdat**.

The **Basis** pane

On the **Config → Output...** dialog, setting "dxplot" to 0 causes each reaction step to be written to "React_plot.gtp". Click **OK**.

Note that **React** carries the reaction path to the point of near complete desiccation, at which point it abandons any attempt to further trace the path; the "error" message produced is expected behavior and can be ignored. The calculation results show the sequence of minerals that precipitate during the evaporation of seawater at 25°C.

3.3 Flush model

A flush model is a special reaction path in which a fluid, added as a reactant, displaces existing fluid from the system. In contrast to the reference frame of a flow-through model, which follows a migrating fluid, a flush model is traced from the reference frame of the rock through which the fluid migrates. Set a flush model from the **Config → Stepping...** dialog, or type the command flush.

- special configurations -	
flow-through	dump
I flush	end-dump
flash off	

To turn off the option, uncheck "flush" or type the command flush off.

To simulate, for example, reaction in a quartzite containing muscovite and microcline as CO₂-charged fluid migrates through it, double-click the "Flush.rea" input file. When **React** opens, go to the **Basis** pane.

Basis Read	tants Medium	Command	Results

the "flush" option has been selected. As a result, the reactant fluid will displace an equal amount of fluid (in terms of water mass) from the system.

3.4 Polythermal reaction paths

React traces polythermal reactions in one of three ways. It can vary temperature linearly from an initial to a final value over a reaction path—such a calculation is called a "sliding temperature" path. The program can also calculate temperature from the mixing of reactants at one temperature into an initial system of another, assuming approximate values for heat capacity. This second option is called a "polythermal mixing" or "quench" model. Finally, the program can account for heat produced or consumed internally in the domain, as described in the **Internal heat production** section of the **GWB Reactive Transport Modeling Guide**. A heat source can be applied in a "normal" path in which you only set the initial temperature of the system, or in conjunction with a "polythermal mixing" path, but not with the "sliding temperature" option. Polythermal paths can trace the simple heating or cooling of a chemical system, or can be combined with other **React** features, such as reactants, kinetic rate laws, and isotopic fractionation.

To set a sliding temperature model, specify initial and final temperatures in the range of the thermo data, typically 0°C–300°C. For example, to simulate cooling, set the system's composition in the usual way and enter the beginning and ending temperatures: click the pulldown next to the unit for temperature on the **Basis** pane, then choose "sliding temperature".

Upon selecting this option, "temperature" will be relabeled "initial temperature" and a new field labeled "slide temperature to" will appear below it.

initial temperature	300.0	▼ C ▼
slide temperature to	25.0	▼ C ▼

In this case, the system begins at 300°C and cools to 25°C. Alternatively, set the sliding temperature path with the command

temperature initial = 300, final = 25

In a polythermal mixing model, set the temperatures for the reactants and the initial system. Over the path, the program calculates the temperature from the mass of reactant that has been added to the system, using the approximate heat capacities for fluids (water) and minerals (rock) stored in variables "cpw" and "cpr" (set on the **Medium** pane; see **Settable variables** in the section **Getting Started with React**). To set the polythermal mixing model, choose "reactant mixing" from the pulldown, then set a value for the "reactant temperature" field that appears.

initial temperature	60.0	•	c 🔻
reactant temperature	200.0	•	c 🔻

In the following example, the program is applied to model a steam flood of a hypothetical petroleum reservoir composed of quartz, illite (muscovite), albite, and (ordered) dolomite. The "steam" here is actually hot water containing CO₂. Double-click on the "Steam.rea" input file. When **React** opens, go to the **Basis** pane,

the "flush" option has been enabled. This setting, combined with the value set for "reactants times" on the **Reactants** pane, causes the hot reactant fluid to pass through the initially cooler formation 20 times.

The figure below shows the calculation results.

The reservoir, initially at 60°C, is progressively heated as the 200°C flood passes through. The horizontal axis represents the number of times the 1 kg of pore water in the system is replaced.

3.5 Buffered paths

React can trace reaction paths in which one or more species activities or gas fugacities are held constant. Values of pH, Eh, and pe may also be fixed. Fixed activity and fixed fugacity paths provide a means of modeling systems buffered in nature by contact with a gas reservoir such as the atmosphere, or in the laboratory by a pH-stat or similar device.

To model a buffered system, fix an activity or fugacity from the **Reactants** pane: click on $\[add \] \rightarrow$ **Fixed**, then select the desired option. Selecting **Aqueous...** or **Gas...** will bring up a pulldown of species to choose from.

reactant	s and kinetic react	ions —		
add	Simple	>	1	
reactants	Fixed	>	рН	1
	Sliding	>	Eh	
	Kinetic	>	pe	
			Aqueous	
			Gas	
			Ratio	

You can also set a buffered path by typing a command such as

fix f CO2(g)

or

In these cases, the program maintains the fluid's CO₂ fugacity and pH at their initial values.

To simulate pyrite dissolving into a water that remains oxidized by contact with the atmosphere, double-click on the "Pyrite.rea" input file. When **React** opens, go to the **Basis** pane

Basis	Reactants	Medium	Command	Results		
constraints	on initial system -

time s	tart 0.0	▼ day	end 1.0	▼ day ▼		

to see the initial composition, which is set to be in equilibrium with O2(g) in the atmosphere.

On the Reactants pane,

E React : Pyrite.rea	—	×
<u>F</u> ile <u>E</u> dit Run Config <u>V</u> iew <u>H</u> elp		
Basis Reactants Medium Command Results		
reactants and kinetic reactions		
+ React 10 mg of Pyrite		
Fix fugacity of O2(g)		
add delete		
reactants times 1.0		
<		>

the fixed O2(g) fugacity buffer ensures that the water remains oxidized as Pyrite is titrated into the fluid.

To hold an activity ratio constant over the course of a reaction path, "fix" the ratio on the **Reactants** pane by clicking on \blacksquare **dd** \rightarrow **Fixed** \rightarrow **Ratio...**

reactant	s and kinetic react	tions —		
add	Simple	>		
reactants	Fixed	>	рН	1
	Sliding	>	Eh	
	Kinetic	>	pe	
			Aqueous	
			Gas	
			Ratio	

then choosing species, and their powers, for the numerator and denominator. For example, the setting below

ξ Species Activ	rity Ratio	×
	Ca++/Na+^	2
Ca++	▼ ^ [1
Na+	• ^ [2
ОК	Apply C	Cancel Reset

or the equivalent command

fix ratio Ca++/Na+^2

holds invariant the activity ratio for calcium and sodium ions to reflect a simple ion exchange buffer.

3.6 Sliding activity and fugacity

React can not only hold species activities and gas fugacities constant, but can vary one or more of these values over a reaction path. Calculations of this type are known as sliding activity paths and sliding fugacity paths. To set a sliding activity or fugacity, move to the **Reactants** pane and choose add \Rightarrow **Sliding**, or use the slide command.

To calculate the effect at 60° C of CO₂ escaping from a groundwater in equilibrium with calcite, for example, double-click on the "Degas.rea" input file. The **Basis** pane

3.7 Surface complexation

The examples in this section show how to incorporate surface complexation into reaction modeling with **React**.

3.7.1 Two-layer model

In a first example, we compute the effect of pH on the surface complexation of a variety of dissolved species, according to the two-layer model. Double-click on the "Surface.rea" input file and when **React** opens go to the **Basis** pane to see the initial fluid composition

sets a sliding pH path. In the calculation results, copper sorption on goethite increases with $\mathsf{p}\mathsf{H}$

Dataset "Goethite_P.rea" lets you carry out calculations of this sort for the NaClO₄-P system in contact with Goethite.

3.8 "Flash diagrams"

You can use **React** to calculate "flash diagrams" of the type employed by reservoir engineers to study scaling. A flash diagram shows the mineral or end member masses that precipitate, or the saturation state of various minerals and solid solutions, when two fluids are mixed in varying proportions. The diagrams do not represent "flashing" in the geochemical sense of gas escaping from a fluid.

In calculating a flash plot, **React** gradually removes the original fluid from the equilibrium system as it titrates in a reactant fluid. Enable the feature from the **Config** \rightarrow **Stepping...** dialog

- special configurations -	
flow-through	dump
🗌 flush	end-dump
flash fluid	

by selecting the "fluid" option from the flash pulldown, or by typing flash. Disable it by selecting "off" from the pulldown, or with the command flash off.

- special configurations -	
flow-through	dump
🗌 flush	end-dump
flash off	

Selecting "system" from the flash pulldown, or typing flash system

— special configurations —	
flow-through	dump
flush	end-dump
flash system 🔻]

removes the initial system, including fluid, minerals, and end members.

For example, the input script "Flash.rea" traces a reaction path representing the mixing of two fluids in all possible mixing ratios. Double-click the file to launch **React**, then move to the **Basis** pane,

Basis Re	eactants	Medium	Command	Results

\geq					=			
start	□ start date 2/ 8/2018							
start	t time	9:41:46	AM					
OK		Apply	Cancel	Reset	t			

the flash option is enabled.

You could have instead used the commands

```
T = 120
Na+ = 27000 mg/kg
Cl- = 42000 mg/kg
S04-- = 1 mg/kg
Ba++ = 400 mg/kg
pH = 5.8
go
pickup reactants = fluid
Na+ = 10800 mg/kg
Cl- = 15500 mg/kg
S04-- = 2000 mg/kg
Ba++ = 100 ug/kg
pH = 6.5
flash = on
go
```

Run → **Go** traces the simulation. Using **Gtplot**, you can plot the mineral mass produced versus extent of mixing.

The horizontal axis shows the extent of mixing from purely the first fluid (left) to purely the second (right); a mixing value of 0.4, for example, represents a mixture of 60% of the first fluid and 40% of the second.

- options Kd	pitation sorbate

use NaCl fluid of sam	ne TDS chlorinity
log K span	
extrapolate	
span min	

By disabling precipitation in the **React** run on the **Config → Options...** dialog,

or by typing precip = off, you can plot mineral saturation states.

3.9 Fractionation of stable isotopes

As described in the **Fractionation of stable isotopes** section of the **GWB Essentials Guide**, the reaction modeling programs in the GWB can account for the equilibrium fractionation of stable isotopes. The GWB is distributed with a database "isotope.dat" containing fractionation factor correlations for the isotopes ²H, ¹³C, ¹⁸O, and ³⁴S. You can augment the database by adding isotopes such as ¹⁷O of those elements, or isotopes like ⁵⁷Fe of other elements.

Program **React** can trace the equilibrium fractionation of stable isotopes over the course of a reaction path. To define an isotopic path, set first the fluid's initial composition and then the isotopic composition of whatever reactants are to be added to the system. You set the isotopic compositions from either the **Config** \rightarrow **Isotopes...** dialog or the **Command** pane.

To trace oxygen fractionation as a system reacts with quartz, for example, begin by adding "Quartz" as a reactant, then enter values for δ^{18} O of the initial fluid as well as the reactant mineral

ξ Isotopes				_		Х
segregated minerals						
- isotopic composition

		OK	Apply	Cancel	Reset	:

Alternatively, type the command

oxygen initial = -5, Quartz = +40

You may specify compositions relative to any isotopic standard, including SMOW, PDB, or CDT. The program predicts over the reaction path isotopic compositions for species, minerals, end members, and gases relative to the same standard, and writes the results to the dataset "React_isotope.txt", as well as to "React_plot.gtp", where it is available for plotting by **Gtplot**.

The program begins by calculating the compositions of solvent and dissolved species to honor the fluid's bulk composition, as specified, assuming isotopic equilibrium among species. The program then sets minerals and end members in the initial system and any buffered gases to compositions in equilibrium with the fluid.

Adding or removing reactants over the course of a reaction path changes the system's isotopic composition. The program responds by redistributing isotopic mass to maintain equilibrium among solvent, aqueous and surface species, and minerals and end members. You specify the compositions of reactants that are added to the system. When reactants are removed, however, the program assumes the composition of the reactant species as it exists at that point in the reaction path.

The calculation as described treats minerals and end members as if they exchange isotopes rapidly enough to remain in equilibrium with the changing system. This assumption, which can be unrealistic, may be relaxed by specifying that a mineral or end member, or some fraction of its mass, remain segregated from isotopic exchange.

A segregated mineral changes composition over a reaction step when it precipitates from solution; the newly precipitated mass forms in isotopic equilibrium with the system, but any of the mineral or end member present at the start of the step is unaffected. Conversely, a segregated mineral affects the system's composition when it dissolves. Note that a kinetic mineral or end member exists outside the equilibrium system and hence behaves isotopically as if it were fully segregated.

To hold a mineral segregated, move to the **Config** \rightarrow **Isotopes...** dialog and select the mineral by clicking add. For an end member, segregate the corresponding mineral. Segregating both minerals making up a solid solution, then, segregates the solution.

For example, you could segregate muscovite and assign its composition at the start of the path as shown below (Note you must set the initial bulk fluid composition for an isotope system before you can use the GUI to set the composition of reactants or segregated minerals in that system).

ξ Isotopes						_		\times
- segregated minerals)
+ Muscovite 100.0%								
add delete								ļ
isotopic composition —— — Hydrogen-2 ———								
initial	1.0	•	‰				dear	
Muscovite	-20.0	•	‰					
Carbon-13								
initial		•	‰				dear	
Oxygen-18								
initial	5.0	•	‰				dear	
Muscovite	30	•	‰					
- Sulfur-34								
initial		•	‰				dear	
			ОК	Apply	Car	ncel	Rese	t

Alternatively, type the commands

```
segregate Muscovite
oxygen Muscovite = +30
hydrogen Muscovite = -20
```

If you do not specify a segregated mineral's composition, and it is present in the initial system, the program will set its composition to be in equilibrium with the initial fluid.

Table 3.2	Isotopic composition of reactants				
Reactant	Mass is being added	Mass is being removed			
Simple reactant	Set by modeler	For existing mineral or end member, its segregated plus unsegregated composition; else, composition in equilibrium with current fluid			
Fixed or sliding buffer	Set by modeler; defaults to equilibrium with initial system $(\xi = 0)$	Isotopic equilibrium with fluid at current point in reaction path			
Kinetic mineral or end member	Set by modeler, unless dissolving mineral is completely within the equilibrium system at $\xi = 0$, in which case the mineral's segregated plus unsegregated composition	Increment in mass of precipitating mineral or end member is in isotopic equilibrium with current system; bulk reactant composition reflects cumulative mass to current point in reaction path			
Kinetic gas transfer	Set by modeler; defaults to equilibrium with initial system	Isotopic equilibrium with fluid at current point in reaction path			
Charge rebalancing	Set by modeler; defaults to equilibrium with initial system	Isotopic equilibrium with fluid at current point in reaction path			

React treats buffered reactants in a manner similar to simple reactants. When added, a buffered species or gas assumes the composition specified by the modeler, or, by default, the composition in equilibrium with the initial system. Upon removal, the buffer takes on the composition in equilibrium with the system at the current point in the reaction path. **Table 3.2** summarizes how **React** assigns isotopic compositions to various types of reactants as it traces a reaction path.

React treats **flush** and **flash** models in the same way: you specify the isotopic composition of each component in the flushing or flashing fluid. In a **flow-through** model, the program reports the isotopic composition of the increment in mineral or end member mass precipitated over the current step, rather than the composition of the cumulative mass.

Consider, as an example, the effects of pyrite dissolving into a groundwater that remains oxidized by contact with the atmosphere. Double-click on the "Isotope.rea" input file to launch **React**. The **Basis** pane

1								

or the command

pickup reactants = minerals

picks up the resulting minerals and end members as a set of reactants.

You can use the pickup feature, as an example, to simulate the mixing of two fluids. To mix fluid 1 (whose composition, pH, etc. are listed in dataset "Fluid1") into fluid 2 (in dataset "Fluid2"), follow the steps

```
read Fluid1
go
pickup reactants = fluid
read Fluid2
reactants times 10
go
```

React equilibrates fluid 1 and takes the fluid's bulk composition as a reactant. The program then equilibrates fluid 2 and reacts about 10 kg of fluid 1 into the second fluid over the course of a reaction path.

The pickup command also allows you to pick up kinetic reactions at their endpoint states, and thus chain together kinetic reaction paths. This feature is discussed in **Chaining together kinetic paths** in the next chapter of this guide.

Kinetic Reaction Paths

In the reaction models discussed to this point, reactants are added to (or removed from) a system at arbitrary rates. **React** can also trace reactions in which kinetic rate laws control the time rates at which reactions proceed.

React can trace the progress through time of several types of kinetic reactions, including

- The dissolution and precipitation of minerals, or solid solution end members
- The dissociation and association of aqueous complexes, or surface complexes
- The transfer of gases from an external reservoir, or into one
- Oxidation and reduction (redox) reactions, in solutions held in redox disequilibrium
- The rate of microbial metabolism and the growth of microbial communities

You can construct a model considering a single kinetic reaction, or one combining several reactions or types of reactions. Kinetic modeling is discussed in detail in the remainder of this section.

4.1 Setting kinetic reactions

To construct a kinetic reaction path, specify the time span of the simulation on the **Basis** pane, or with the time command. Then set one or more kinetic reactions, either on the **Reactants** pane (click add and the appropriate option) or using the kinetic command. In this way, you define the specifics of the rate law, such as the rate constant to be used, reaction orders, and so on. Table 4.1 summarizes the keywords that can be used to define kinetic reactions.

Table 4.1 Summary of keywords for the kinetic command. Symbol ✓ indicates that for the applicable reaction types, a value for the keyword must be set. For symbol *, note the following: (1) an activation energy and a pre-exponential constant can be specified in place of a rate constant; (2) a value for surface must be set for redox reactions considering a heterogeneous catalyst; (3) a value for KA is required for enzymatically promoted reactions; and (4) a value for mE or aE is required when modeling enzyme kinetics. For symbol †, note: (1) units shown for rate_con and pre-exp are in the absence of promoting and inhibiting species, as set with apower or mpower keyword; (2) units for KA and KD depend on settings for mpowerA and mpowerD. Use keywords apower, apowerA, and apowerD to set a species' activity in rate law, and mpower, mpowerA, and mpowerD to set its molality.

The rate law for each type of kinetic reaction is coded within **React** in a form sufficiently general to support most applications in geochemistry. This form is the "built in" rate law. You may, furthermore, specify the form of a rate law directly. **React** evaluates the rate law you set using an internal interpreter. For example, after adding the kinetic mineral quartz from the **Reactants** pane, you could change the rate law pulldown from "built in" to "equation" and then set the form directly, as in the box below.

rate law	equation	dissolution	Oprecipitation	
	rate_con * s	surface * (1 - Q/K)		Ŧ

The equation prescribes a rate law of the form shown, for the dissolution and precipitation of quartz. On the **Command** pane, you would type

kinetic Quartz rate law = "rate con * surface * (1 - Q/K)"

You can also write basic scripts to calculate reaction rates, and even write and compile C++ functions that **React** links to and executes at run time. Methods for setting custom rate laws are described in detail in the next section of this guide, **Custom Rate Laws**.

At each point in a simulation, **React** selects a time step short enough to accurately trace each kinetic reaction considered, and to ensure numerical stability. Introducing kinetic rate laws can sometimes lead to lengthy runs, for this reason, if the time span of the simulation is long relative to the characteristic times of the kinetic reactions considered. Calculating a simulation spanning millions of years, for example, might require a lot of computing time if the run includes kinetic reactions that approach equilibrium within a few days.

To constrain a time step, the program allows only a small change in the relative value of the ion activity product (i.e., in $\Delta Q/Q$) for each kinetic reaction. The limiting projected change in this quantity is by default 0.1, but you can set your own criterion, as described below. Setting a value larger than the default can lead to longer time steps, whereas a smaller value might improve stability by forcing smaller steps. You can also constrain the time step directly by adjusting the variable "delxi".

A time weighting variable θ , which can range from 0 to 1, controls the method **React** uses to integrate rate laws. When θ is 0, the integration proceeds by evaluating reaction rates only at the start of each time step, whereas a θ value of 1 causes the rates to be figured at the step's end, as part of the Newton-Raphson iteration. Prescribing an intermediate value sets a weighted average of the rates, before and after. Values close to one-half give runs that are more stable numerically than when $\theta = 0$, and lead to less truncation error than when θ is either 0 or 1. In **React**, the default value is 0.6.

Values "delQ", "delxi", and "theta" are examples of "settable variables," as described under **Settable variables** in the **Getting Started with React** section of this guide. You can alter these values directly from the command line or using a script, or on the **Config** → **Stepping...** dialog. To constrain the time stepping tightly, for example, you might reduce the value for "delQ" by a factor of 10 by changing the value to 0.01

Kinetic Reaction Paths 71

or type delQ = 0.01. The command show variables lists the settable variables and their current values.

4.2 Kinetics of precipitation and dissolution

A simple rate law for mineral dissolution and precipitation takes the form

$$r_{\vec{\kappa}} = A_S k_+ \left(1 - \frac{Q}{\kappa} \right) \tag{4.1}$$

Here $r_{\vec{k}}$ is reaction rate (mol s⁻¹, positive for dissolution), A_S is the mineral's surface area (cm²), k_+ is the rate constant (in mol cm⁻² s⁻¹), and Q and K are the activity product and equilibrium constant for the dissolution reaction.

By this equation, a mineral precipitates when it is supersaturated and dissolves when it is undersaturated at a rate that depends on its rate constant and surface area. **React** calculates surface area from a specific surface area in $\text{cm}^2 \text{ g}^{-1}$ entered by the user for each kinetic mineral. The user also supplies the value of the rate constant, or an activation energy E_A and pre-exponential factor A for the Arrhenius equation

$$k_{+} = A \, e^{-E_{A}/RT_{K}} \tag{4.2}$$

so that the program can determine k_+ as temperature varies. Here, R is the gas constant and T_{κ} is the absolute temperature in Kelvins. There is provision in **React** for more complicated rate expressions than the rate law above, such as those in which the rate law accounts for promoting and inhibiting species in solution, as discussed later.

You can set kinetic rate laws for minerals swapped into the initial system and thus initially in equilibrium with the fluid, as well as for minerals set as reactants. However, a kinetic mineral must exist in some amount (or a nucleation term must be set, as described below); otherwise, its surface area will be 0 and it will never precipitate.

As an example, trace the kinetic dissolution of albite at 70°C into a water in equilibrium with kaolinite, muscovite, and quartz, assuming that the reaction of quartz is also controlled kinetically. Open "Kinetic.rea" and move to the **Basis** pane.

<								>

On the **Reactants** pane, expand the "Kinetic" fields for the two minerals.

Rate constants of 10^{-15} and 2×10^{-16} mol cm⁻² s⁻¹ are set for albite and quartz, and a specific surface area of 10^3 cm² g⁻¹ is set for each mineral.

If working from the **Command** pane, type

```
T = 70
swap Kaolinite for Al+++
swap Quartz for SiO2(aq)
swap Muscovite for K+
PH = 6
Na+ = .3 molal
Ca++ = .05 molal
Cl- = .3 molal
HCO3- = .02 molal
10 free g Kaolinite
100 free g Quartz
10 free g Muscovite
```

```
(cont'd)
react 25 g "Albite low"
kinetic "Albite low" rate_con = 1e-15 surf = 1e3
kinetic Quartz rate_con = 2e-16 surf = 1e3
time begin 0 yr, end 1500 yr
go
```

Run → Go traces the simulation. The results

show that albite reaches equilibrium twice in the calculation, once in the presence of tridymite and again in the presence of quartz.

Each end member in a continuous solid solution can be similarly set to react according to a kinetic rate law. The activity product *Q* carried in the rate law in this case accounts for the end member's activity, rather than the unity activity of the corresponding mineral.

4.2.1 Promoting and inhibiting species

The kinetic rate law carried to this point can be generalized to account for the effects of promoting and inhibiting species. In this case, the law takes the form

$$r_{\vec{k}} = A_S k_+ \prod_j \left(a_j | m_j \right)^{p_j} \left(1 - \frac{Q}{K} \right)$$
(4.3)

Here \prod is the product function (the multiplicative equivalent of the summation function Σ), a_j and m_j are the activity and molality of each promoting or inhibiting species (the notation " a_j/m_j " signifies that either the species activity or molality is carried), and p_j is that species' "power" in the rate law.

A promoting species has a positive value for p_j , and an inhibiting species has a negative value. When there are no promoting or inhibiting species, this rate law reduces to the previous form. Aqueous species, minerals (represented in the rate law by unit activity or by molality), end members (represented by activity or mole fraction), gas species (represented by fugacity or partial pressure), surface complexes (represented by the species' molality), and solvent water (represented by activity) can serve as promoting and inhibiting species.

To set the promoting and inhibiting species in a rate law, click the <u>add</u> button within the "power" section of the kinetic reactant and choose a species from the pulldown list.

power		
add	Aqueous	
add de	Mineral	
	Gas	
reactants tim	H2O	
	1120	

Set a value for the "power" (the default is 1), then choose whether the species activity

power		
power(H+)	1.0 O molality	
add delete		

or molality should be evaluated in the rate law by selecting the appropriate button.

power	\sim	
power(H+)	1.0 • activity • molality	
add delete		

From the **Command** pane, use the apower or mpower (also apow or mpow) keyword within the kinetic command to set the species activity or molality, respectively, in the rate law. For an end member, keyword apower sets the term as activity and xpower sets it

as mole fraction. For a gas species, keywords fpower and ppower set the term as fugacity or partial pressure, in bar. The generic keyword power sets the solvent or an aqueous species in terms of activity, an end member as activity, a gas as fugacity, and a surface species in terms of molality.

go
```

The rate law assumes that H⁺ acts as a promoter, the activity of which is raised to a power of one. The example includes a single promoting species, but you can set for each rate law as many promoting and inhibiting species as you desire.

4.2.2 Nonlinear rate laws

React can also treat rate laws of the nonlinear form

$$r_{\mathcal{R}} = \operatorname{sgn}\left(1 - \frac{Q}{K}\right) A_{S} k_{+} \prod_{j} \left(a_{j} | m_{j}\right)^{p_{j}} \left|1 - \left(\frac{Q}{K}\right)^{\omega}\right|^{\Omega}$$
(4.4)

Here, sgn is a function returning -1 or +1, depending on the sign of its argument, and variables ω and Ω are the "orders" of the rate law, which define the nonlinearity. When both orders are set to 1, the form of the rate law reduces to the previous form.

Set ω and Ω with keywords "order1" and "order2". As an example, open "Nonlinear.rea". The **Basis** pane

React : Nonlinear.rea			- 🗆 ×	<

describes the dissolution of quartz at 100°C, taking a value of 2 for ω and 1 for Ω .

4.2.3 Cross-affinity rate laws

React supports the use of "cross-affinity" rate laws, in which the saturation state (i.e., Q/K) of one mineral is used to calculate the reaction rate of another mineral (or of an end member). Rate laws of this form are useful for studying problems such as glass dissolution, where reaction of an altered surface layer appears to control the overall dissolution rate.

To set the cross-affinity option, choose a mineral from the pulldown next to "xaffin".

xaffin	off Mineral
power -	off
add	delete

For a purely hypothetical example, the cross-affinity setting in tridymite's rate law below

reactants and kinetic reactions		
- Kinetic Tridymite	0.0	▼ mmol/kg ▼
surface area	+	▼ cm2/g
 rate constant 	+	✓ mol/cm2 sec
Opreexp	+	▼ mol/cm2 sec
activation energy	+	▼ J/mol

nucleus density	+ 0.0	▼ cm2/cm3
critical saturation index	+ 0.0	*
xaffin	Cristobal	balite 🔻
power		
add delete		

causes the program to calculate the reaction rate of tridymite according to the fluid's saturation state with respect to the mineral cristobalite. Alternatively, type

kinetic Tridymite xaffin = Cristobalite

Selecting "off"

xaffin	Cristobalite 🔻	Mineral
power		off
add delete		011

or typing

```
kinetic Tridymite xaffin = OFF
```

turns off the option.

4.2.4 Nucleation

You can set for any kinetic mineral or end member a simple description of nucleation. This feature allows minerals not present in the chemical system to form according to kinetic rate laws. In the absence of a treatment for nucleation, a new kinetic mineral would not be

able to form because its surface area A_s would be 0, leading to null reaction rates according to the rate laws.

To set the surface area (in $\text{cm}^2 \text{ cm}^{-3}$ fluid volume) available in the chemical system for nucleation whenever a mineral is supersaturated, enter a value for "nucleus density" in the kinetic rate law for that mineral.

nucleus density	+	0.0	•	cm2/cm3	
-----------------	---	-----	---	---------	--

This option prescribes a minimum value for a supersaturated mineral's A_s over the calculation. For example, the setting below

reactants and kinetic reaction	S		
- Kinetic Quartz	0.0	▼ mmol/kg ▼	
surface area	+	✓ cm2/g	
rate constant	+	▼ mol/cm2 sec	
Opreexp	+	▼ mol/cm2 sec	
activation energy	+	▼ J/mol	
rate law	+ built in	▼	
	order 1 1.0	▼ order 2 1.0 ▼	
nucleus density	+ 100.0	✓ cm2/cm3	
critical saturation index	+ 0.0	▼	
xaffin		off 🔻	
add delete			

or the command

```
kinetic Quartz nucleus = 100
```

prescribes that, per cm³ of fluid, 100 cm² of surface area is available for the growth of quartz. By default, the nucleation area is 0.

In addition, you can set a critical saturation index (log Q/K) for a mineral or end member. In this case, the mineral's nucleation area is available only when its saturation index exceeds the prescribed value. Set this option using "critical saturation index"

nucleus density	+ 100.0	▼ cm2/cm3	
critical saturation index	+ 0.1	\triangleright	

or the CritSI keyword.

kinetic Q	uartz	nucleus	=	100,	CritSI	=	0.1	
-----------	-------	---------	---	------	--------	---	-----	--

The example above makes the nucleation area for quartz available only when the mineral has a saturation state \ge 0.1. The default value for this option is 0, which means that the prescribed nucleation area is available whenever the mineral is supersaturated.

4.3 Forward and reverse reactions

In **React**, you most commonly set a kinetic law describing the forward rate of a reaction. In this case, a positive $r_{\overrightarrow{r}}$ indicates a mineral or end member is dissolving, a complex dissociating, a gas dissolving into the fluid, or a redox or microbial reaction proceeding from left to right. You can alternatively specify that evaluating the rate law gives a positive result for the reverse reaction: precipitation, association, gas exsolution, or right-to-left progress.

The dissolution of quartz

$$SiO_2(qtz) \rightarrow SiO_2(aq)$$
 (4.5)

for example, might be described by the rate law

$$r_{\vec{K}} = A_S k_+ \left(1 - \frac{Q}{K}\right) \tag{4.6}$$

where $r_{\vec{k}}$ is dissolution rate, A_s is surface area, k_+ is the rate constant, and Q and K are the reaction's activity product and equilibrium constant. Taking k_+ at 70°C to be 2 × 10⁻¹⁶ mol cm⁻² s and A_s as 10³ cm² g⁻¹, you can set this rate law from the **Reactants** pane as shown below

ξ React							
<u>File Edit Run Config Vie</u>	<u>F</u> ile <u>E</u> dit Run Config <u>V</u> iew <u>H</u> elp						
Basis Reactants	Medium C	ommand Results					
reactants and kinetic reactions							
- Kinetic Quartz	0.0	▼ mmol/kg ▼					
surface area	+ 1000.0	▼ cm2/g					
rate constant	+ 2.0e-16	▼ mol/cm2 sec					
Opreexp	+	▼ mol/cm2 sec					
activation energy	+	▼ J/mol					
rate law	+ built in	▼					
	order 1 1.0	▼ order 2 1.0 ▼					
nucleus density	+ 0.0	▼ cm2/cm3					
critical saturation index	+ 0.0	T					
xaffin		off 🔻					
add delete							

or by typing

kinetic Quartz forward rate con = 2e-16 surf = 1000

Selection of the "dissolution" option specifies that the law describes the dissolution (forward) reaction, which is the default behavior.

If we write the reverse reaction, for precipitation,

$$SiO_2(qtz) \leftarrow SiO_2(aq)$$
 (4.7)

the activity product $\overleftarrow{Q} = 1/Q$ and the equilibrium constant $\overleftarrow{K} = 1/K$. Noting that $K = k_+/\overleftarrow{k_+}$ is the ratio of the rate constants for the forward and reverse reactions, and that $Q = a_{SiO_2(aq)}$, the rate law for this reaction is

$$\tilde{r}_{\vec{k}} = -r_{\vec{k}} = A_S \,\tilde{k}_+ \, a_{\text{SiO}_2(\text{aq})} \left(1 - \frac{\dot{Q}}{\ddot{K}} \right) \tag{4.8}$$

K at 70°C is $10^{-3:39}$, so \overleftarrow{k}_{+} is 4.9×10^{-13} .

    rate con = 2e-12 surf = 1000 apower(SiO2(aq)) = 1
```

sets this law, which is equivalent in function to the forward law described previously.

4.4 Kinetics of complexation and sorption

React can trace the association and dissociation of any number of aqueous complexes, as well as surface complexes. The program uses a built-in rate law of the form

$$r_{\vec{k}} = n_{w} k_{+} \prod_{j} \left(a_{j} \mid m_{j} \right)^{p_{j}} \left(1 - \frac{Q}{K} \right)$$
(4.9)

to calculate the reaction rate $r_{\mathcal{R}}$, in mol s⁻¹. Here, n_w is kg of solvent water, k_+ is the intrinsic rate constant (molal s⁻¹, in the absence of promoting and inhibiting species), p_j are powers

applied to the activities *a_j* or molalities *m_j* of the **promoting and inhibiting species**, and *Q* and *K* are the reaction's ion activity product and equilibrium constant.

Reactions in **React** are written for species dissociation, so if you set a rate law for a forward reaction (see previous section, **Forward and reverse reactions**), $r \neq r$ is positive when the complex decomposes. The built-in law can assume the **nonlinear form**,

$$r_{\vec{k}} = \operatorname{sgn}\left(1 - \frac{Q}{K}\right) n_{w} k_{+} \prod_{j} \left(a_{j} \mid m_{j}\right)^{p_{j}} \left|1 - \left(\frac{Q}{K}\right)^{\omega}\right|^{\Omega}$$
(4.10)

in which ω and Ω are the nonlinearity coefficients, or reaction orders. When you set either nonlinearity coefficient to a value other than 1, the program uses the nonlinear law. You can, of course, set your own rate equation, rather than using the built-in law.

Set the initial concentration of a kinetic complex directly within its entry on the **Reactants** pane

reactants and kinetic reactions		
- Kinetic CaSO4	200.0	▼ umolal ▼

or by typing

kinetic CaSO4 200 umolal

The input specifies a 200 μ molal concentration for the CaSO₄ ion pair, at the beginning of the run. Note that the basis must be set to contain at least this much total calcium and sulfate, or the program will not be able to distribute mass. If you do not set an initial concentration, or set it to ?, the program will take the complex at the onset of the run to be in equilibrium with the initial fluid.

In **X1t** and **X2t**, click \bullet to expand the "fluid concentrations" box, then set the concentration of the kinetic complex in each boundary fluid:

reactants and kinetic reactions Kinetic PbPO4-	+ equil	▼ mmol/kg ▼
- fluid concentrations		
my_boundary	0.3	▼ umolal ▼
my_injection	equil	▼ mmol/kg ▼

Alternatively, type

kinetic PbPO4- my boundary = 0.3 umolal, my injection = ?

As with the initial fluid, if you omit this setting, or specify an argument of ?, the complex will be set to its equilibrium concentration.

As an example, the complexation of aluminum and fluoride ions

$$AIF^{++} \leftarrow AI^{+++} + F^{-} \tag{4.11}$$

can be described by the rate law

$$\frac{dm_{AlF^{++}}}{dt} = \frac{\tilde{r}_{\vec{k}}}{n_w} = \tilde{k}_+ m_{Al^{+++}} m_{F^-} \left(1 - \frac{\bar{Q}}{\bar{k}}\right)$$
(4.12)

Open the "Association.rea" input file and move to the **Basis** pane,

ystem

Set a pH buffer and the rate law for calcium desorption. Take a rate constant k_+ of 2 × 10⁻⁴ s⁻¹, and the initial concentration of the surface complex to be 1500 μ molal. The results are show here.

4.5 Gas transfer kinetics

React can account for the kinetics of gas transfer between a fluid and an external gas reservoir, such as the atmosphere. The program calculates the rate $r_{\vec{k}}$ (mol s⁻¹) at which a kinetic gas $A_{\vec{k}}$ dissolves into a fluid using the built-in equation

$$r_{\vec{k}} = n_w A_{sp} k_+ (f_{ext} - f_{\vec{k}})$$
(4.15)

Here, n_w is solvent mass (kg), k_+ is the rate constant (mol cm⁻² s⁻¹), A_{sp} is the specific contact area (cm² [kg solvent]⁻¹) between reservoir and fluid, and f_{ext} and $f_{\vec{k}}$ are the fugacities of $A_{\vec{k}}$ in the external reservoir and the fluid. Where gas exsolves from the fluid, $r_{\vec{k}}$ is negative.

Parallel to the other kinetic features, you can specify **promoting and inhibiting species**, in which case, the law takes the form

$$r_{\vec{k}} = n_{w} A_{sp} k_{+} \prod_{j} (a_{j} | m_{j})^{p_{j}} (f_{ext} - f_{\vec{k}})$$
(4.16)

You can set a nonlinear law

$$r_{\vec{k}} = \operatorname{sgn}(f_{ext} - f_{\vec{k}}) n_{w} A_{sp} k_{+} \prod_{j} (a_{j} | m_{j})^{p_{j}} |f_{ext} - f_{\vec{k}}|^{\Omega}$$
(4.17)

in which Ω is the nonlinearity coefficient (there is no ω in the gas transfer model). And, as before, you can specify your own rate equation, instead of using the built-in law.

To set up kinetic gas transfer, you generally set the gas' fugacity f_{ext} in the external reservoir, or its partial pressure $P_{ext'}$ there; the model converts a pressure value to fugacity internally. You furthermore set the contact area between the fluid and external reservoir, in units of cm² (kg solvent)⁻¹.

On the **Reactants** pane, at the top of the field for a gas transfer reaction, you constrain the external reservoir by entering a value and choosing either "fugacity" or a unit of pressure from the pulldown. Working from the command line, use the f_ext keyword to set external fugacity, and p_ext plus an optional unit to set partial pressure; the default unit is bar.

If you do not specify a value for external fugacity, the program takes it as the gas' fugacity in the initial system, at the onset of reaction. Finally, you set the contact area on the next line in the **Reactants** pane, or with the contact keyword on the command line.

Having added a kinetic gas reaction, the **Reactants** pane might look like

ξ React			
<u>F</u> ile <u>E</u> dit Run Config	j <u>V</u> iew <u>H</u> elp

add delete			

Alternatively, we might type the command

kinetic O2(g) f_ext = 0.2, contact = 5, rate_con = 3.4e-7

These cases set up a kinetic reaction for the transfer of $O_2(g)$ between the fluid and an external reservoir in which f_{O_2} is 0.2. The contact area A_{sp} in this case is 5 cm² (kg solvent)⁻¹ and the rate constant k_+ is 3.4×10^{-7} mol cm⁻² s⁻¹.

As a worked example, we trace the degassing of CO_2 from a well-mixed surface water. Open "GasTransfer.rea" and go to the **Basis** pane

and set the details of the kinetic rate law. The f_{CO_2} in the atmosphere is $10^{-3.5}$. The water is 125 cm deep, so A_{sp} is 8 cm² (kg solvent)⁻¹, and assume a rate constant k_+ of 2 × 10^{-7} mol cm⁻² s⁻¹. The results are shown here.

4.6 Kinetics of redox reactions

You can use **React** to trace the progress over time of redox reactions, as described by kinetic rate laws. There is no limit to the number of kinetic redox reactions you can consider in a single simulation.

The kinetic rate law for a redox reaction is often presented in the form,

$$r_{\vec{k}} = n_{w} k_{+} \prod_{j} (a_{j} | m_{j})^{p_{j}}$$
(4.18)

where n_w is the mass of solvent water (kg), and k_+ is the intrinsic rate constant (expressed in molal s⁻¹). The product function \prod in this equation accounts for the **promoting and inhibiting species** *j* in the rate law; the activity or molality of each such species appears raised to its power p_j . Each of these species may be an aqueous species, mineral, end member (in which case it is represented by its activity or mole fraction), surface species (by molality), gas (by fugacity or partial pressure), or solvent (by activity).

If this equation is generalized to account for reverse as well as forward reaction, it takes the form,

$$r_{\vec{k}} = n_{w} k_{+} \prod_{j} \left(a_{j} | m_{j} \right)^{p_{j}} \left(1 - \frac{Q}{K} \right)$$
(4.19)

where *Q* and *K* are the reaction's activity product and equilibrium constant. This equation may in turn be generalized into a **nonlinear form**,

$$r_{\vec{k}} = \operatorname{sgn}\left(1 - \frac{Q}{K}\right) n_{w} k_{+} \prod_{j} \left(a_{j} | m_{j}\right)^{p_{j}} \left|1 - \left(\frac{Q}{K}\right)^{\omega}\right|^{\Omega}$$
(4.20)

where ω and Ω are the nonlinearity coefficients (the rate law orders). This is the general form of the rate law that **React** carries for redox reactions.

To set up a kinetic redox reaction, begin by decoupling the redox couple in question, so that the reaction is not in equilibrium initially. Then set up the kinetic reaction and the form of the rate law.

couples O coupling reaction	ns		select with	•	inver	t selectio
ClO4'/Cl' Co+++/Co++ Cr+/Co+++ Cr04''/Cr+++ Cr04''/Cr+++ Cr04'''/Cr+++ Eu++/Eu+++ H2(a0)/H+ Hg2++/Hg++ HS'/SO4''	^	decouple >> decouple all << couple couple all	Fe+++/Fe++			

As an example, go to the **Config** \rightarrow **Redox couples...** dialog and decouple the Fe⁺⁺⁺/Fe⁺⁺ pair,

then move to the **Reactants** pane and click \rightarrow **Kinetic** \rightarrow **Redox reaction**, supplying the info below.

The "fix pH" and "fix fugacity of O2(g)" options simulate reaction in a pH-buffered laboratory experiment left open to oxygen in the atmosphere.

Click on the + button next to reactant "redox-1" to expand its entry. The reaction by which the ferrous iron component oxidizes has been written out explicitly as a character string that the program will read and interpret. If the kinetic reaction hadn't already been created, you would click on add \rightarrow Kinetic \rightarrow Redox reaction to do so.

To keep the discussion simple for the moment, the iron minerals Goethite, Hematite, and Magnetite are suppressed, each of which is more stable and slower to form than ferric hydroxide precipitate.

Suppress	select with
unsuppressed (BaO)2^(SO2)3(c) (BaO)2^SO2(c) (NpO2)2(OH)2^++ (NpO2)3(OH)5^+ (PuO2)2(OH)2^++ (PuO2)3(OH)3^+ (UO2)2(OH)3^+ (UO2)2(OH)3^+ (UO2)2(OH)4^++ V	ppress >> Goethite Hematite unsuppress all

Select **Run** \rightarrow **Go** to calculate the model. The figure below shows the results of modeling the oxidation of ferrous iron by dioxygen, according to a kinetic rate law.

React can also account for the effects of heterogeneous catalysis, enzymes, and biological activity on the rates of redox reactions; these features are described in the following sections.

4.6.1 Catalysis on mineral surfaces

React can account for the catalytic effects of mineral surfaces on **redox reactions**. The rate law in this case

$$r_{\vec{k}} = A_{S} k_{+} \prod_{j} \left(a_{j} | m_{j} \right)^{p_{j}} \left(1 - \frac{Q}{K} \right)$$
(4.23)

Λ

is of the form of the previous equation, with the additional term A_s , which represents the surface area (cm²) of the catalyst. The rate constant k_+ here, in the absence of **promoting and inhibiting species**, is given in units of mol cm⁻² s⁻¹. The rate law in **nonlinear form** is

$$r_{\vec{k}} = \operatorname{sgn}\left(1 - \frac{Q}{K}\right) A_{S} k_{+} \prod_{j} \left(a_{j} | m_{j}\right)^{p_{j}} \left|1 - \left(\frac{Q}{K}\right)^{\omega}\right|^{2}$$
(4.24)

Again, this law is the same as the previous nonlinear form, with the additional term As.

You set a catalytic redox reaction in the "catalyst" section of the rate law. Set the "catalyst" to the name of the mineral serving as a catalyst,

(-reactants and kinetic reaction	s				
	- Kinetic redox- 1	▼				
	reaction					
	 rate constant 	+	 mol/cm2 sec 			
	Opreexp	+	 mol/cm2 sec 			
	activation energy	+	▼ J/mol			
	rate law	+ built in	 Intervation Intervation Intervation 	Orev	erse	
		order 1 1.0	~	order 2	1.0	•
	catalyst	Goethite	$\overline{}$			
	catalytic area	+	▼ cm2/g			
or si	imply to "on".					
	catalyst	on	$\overline{}$			
	catalytic area	+	cm2			

Or, use the catalyst keyword in a kinetic command

```
kinetic redox-1 catalyst = Goethite
kinetic redox-1 catalyst = on
```

Setting a value of "off" disables the feature.

Set the catalyzing surface area using the "catalytic area" field

or by typing

kinetic redox-1 surface = 20

If you have set a specific mineral as the catalyst, its surface area is set in $\text{cm}^2 \text{ g}^{-1}$; the program calculates total surface area from this value and the mineral mass, as it varies over the simulation. If you have simply set "catalyst" to "on", on the other hand, the total catalyzing surface area is set in cm².

Note that it is possible to set parallel pathways for the same redox reaction. Reaction "redox-1", for example, could represent the reaction kinetics in the absence of a catalyst, and "redox-2", the catalyzed reaction. The total reaction rate would be the sum of the rates for "redox-1" and "redox-2".

The following procedure shows an example of how to incorporate redox catalysis into a **React** simulation. Here, the oxidation of Mn⁺⁺ to manganite (MnOOH) by molecular oxygen is catalyzed on the surface of ferric hydroxide.

Double-click on file "Catalysis.rea" and go to the **Config** \rightarrow **Redox couples...** dialog.

Redox couples		select with	inver	L t selection	×
coupled	decouple >> decouple all << couple couple all	decoupled (O-phth) /HCO ₃ Am ⁺⁺⁺⁺ /Am ⁺⁺⁺ AmO ₂ ⁺⁺ /Am ⁺⁺⁺ AmO ₂ ⁺⁺ /Am ⁺⁺⁺ Ash ₃ (aq)/As(OH) ₄ AsO ₄ /As(OH) ₄ Au ⁺⁺⁺ /Au ⁺ CH ₃ COO ⁻ /HCO ₃ CH ₄ (aq)/HCO ₃ ClO ₄ ⁻⁺ /Cl			
	OK	Apply Can	cel	Rese	t

Note how we've disabled all redox coupling reactions. Alternatively, individual reactions can be decoupled: those between ferrous and ferric iron, as well as the reactions between several oxidation states of manganese. Either way, iron and manganese in the simulation can change redox state only by kinetic reaction.

Look at the **Basis** pane.

On the **Config → Suppress...** dialog

note that various iron and manganese minerals have been suppressed because they are stable, but unlikely to form over the time span of the simulation.

Select **Run → Go** to calculate the model.

4.6.2 Enzymes and biotransformations

React can trace the progress of enzymatically or biologically promoted redox reactions. In considering the effects of enzymes, the most commonly encountered rate law is the Michaelis-Menten equation. This equation may also be used in simple cases to model biotransformations (microbes are sometimes referred to as "bags of enzymes").

To construct more sophisticated models of enzymatic and the microbe-mediated reactions, especially for cases in which microbial populations vary with time, see the section **Microbial metabolism and growth**, below.

The Michaelis-Menten equation represents the reaction of a substrate A with an enzyme E to form an activated complex EA, which decomposes irreversibly to give the reaction product P and return the enzyme:

$$A + E \stackrel{k_{i}}{\longleftrightarrow_{k_{j}}} EA \stackrel{k_{s}}{\longrightarrow} P + E$$
(4.25)

The corresponding rate equation takes the well-known form,

$$r_{\vec{k}} = n_w \, k_+ \, m_E \, \frac{m_A}{m_A + K_A} \tag{4.26}$$

where k_+ is the intrinsic rate constant ($k_+ = k_3$, in s⁻¹), m_E is the molal concentration of the enzyme, m_A is the substrate concentration, and K_A is the half-saturation constant

$$\kappa_{A} = \frac{k_{2} + k_{3}}{k_{1}} \tag{4.27}$$

in molal units. The product $k_{+} * m_{E}$ is the maximum reaction rate (molal s⁻¹), commonly denoted r_{max} or v_{max} .

The reaction can be generalized by including the back reaction of products with enzyme to form the activated complex:

$$A + E \xleftarrow[k_2]{k_2} EA \xleftarrow[k_3]{k_3} P + E$$
(4.28)

The rate law in this case takes the form,

$$r_{\vec{k}} = n_{w} k_{+} m_{E} \frac{\frac{m_{A}}{K_{A}}}{1 + \frac{m_{A}}{K_{A}} + \frac{m_{P}}{K_{P}}} \left(1 - \frac{Q}{K}\right)$$
(4.29)

where K_P is the half-saturation constant

$$K_P = \frac{k_2 + k_3}{k_4} \tag{4.30}$$

for the reverse reaction, in molal, and m_P is the molal concentration of reaction product P. Note that when P is at small concentration, Q becomes small also, and the rate law reduces to the Michaelis-Menten equation.

React carries a generalized rate law to model enzymatic reactions and biotransformations. The rate law in linear and nonlinear forms is given as

$$r_{\vec{k}} = n_{w} k_{+} \prod_{j} \left(a_{j} | m_{j} \right)^{p_{j}} m_{E} \frac{\frac{m_{A}}{K_{A}}}{1 + \frac{m_{A}}{K_{A}} + \frac{m_{P}}{K_{P}}} \left(1 - \frac{Q}{K} \right)$$
(4.31)

and

$$r_{\vec{k}} = \operatorname{sgn}\left(1 - \frac{Q}{K}\right) n_{w} k_{+} \prod_{j} \left(a_{j} | m_{j}\right)^{p_{j}} m_{E} \frac{\frac{m_{A}}{K_{A}}}{1 + \frac{m_{A}}{K_{A}} + \frac{m_{P}}{K_{P}}} \left|1 - \left(\frac{Q}{K}\right)^{\omega}\right|^{\Omega}$$
(4.32)

You set the reaction to be modeled using the $r \times n$ keyword, as before. It is important to note that the program takes the first species on the left of the reaction to be the limiting substrate, and the first species on the right to be the limiting reaction product (i.e., the limiting substrate for the reverse reaction). The program tracks the concentrations of these species over the course of the simulation and uses them as the values for m_A and m_P .

For example, in the following input

the acetate is the limiting substrate, and methane is the limiting product. Throughout the simulation, the program will use $m_{CH3COO-}$ as m_A , and $m_{CH4(aq)}$ as m_P . If we were to reverse the order of the species on the right of the reaction, however, the program would take m_{HCO3-} as m_P . The way you write the redox reaction, therefore, affects the modeling results.

Set the identity of the enzyme using the pulldown next to "enzyme" (or use the mE keyword). You can select **Aqueous...** from the pulldown,

enzyme	off 🔻	Aqueous	▼ ○ activity ● molality
Ка	•	on	•
power		off	

then choose an aqueous species in the simulation from the list. In this case, the program, over the course of the simulation, finds the molality of this species and uses it as m_{E} .

enzyme	Ag+ 🔻	mE	▼ ○ activity ● molality
Ка	•	Кр	▼

Alternatively, select "on" from the pulldown to set the enzyme molality to a constant value, which you enter in the "mE" field.

enzyme	on 🔻	mE	1.0	▼ ○ activity	molality
Ка	•	Кр		~	

By selecting "activity" instead of "molal" (or using keyword aE in place of mE), you can specify the activities rather than molalities of the enzyme and the limiting reactant and product species to be used to evaluate the rate law. In this case, the program replaces variables m_E , m_A , and m_P in the rate law shown above with a_E , a_A , and a_P .

enzyme	on 🔻	aE	1.0	O activity O molality
Ка	•	Кр		•

Setting "enzyme" to "off" disables the feature.

enzyme	off 🔻	mE	▼ ○ activity
Ка		Кр	▼

You set the values for the half-saturation constants K_A and K_P in molal units using the "Ka" and "Kp" fields

enzyme	on 🔻	mE	▼) activity molality
Ка	▼	Кр	▼

(or the KA and KP keywords from the command pane), but you can omit a value for K_P , in which case the program will not carry the m_P/K_P term in the rate equation.

The following example models the biotransformation of acetate to bicarbonate by reaction with molecular oxygen, in an experiment open to atmospheric O_2 and CO_2 . Double-click on file "Enzyme.rea" and go to the **Config** \rightarrow **Redox Couples...** dialog.

(O-phth)-'/HCO3- Am++++ Am++++/Am+++ AmO2+/Am+++ AmO2+/Am+++ AmO2+/Am+++ AmO2++/Am+++ AsH3(aq)/As(OH)4-	lecoupled H ₃ COO ⁻ /HCO ₃ ⁻

Move to the **Reactants** pane and expand the entry for reactant "redox-1".

Fix the pH and O₂(g) fugacity to simulate an experiment open to the atmosphere. Taking a value of 8×10^{-6} molal s⁻¹ for r_{max} , configure the simulation by setting "mE" to an arbitrary value of 1, and then k_+ to the value of r_{max} , since $r_{max} = k_+ * m_E$, as described earlier.

Alternatively, type

```
time end = 1 hr
decouple CH3COO-
CH3COO- = 0.2 mmolal
pH = 7
10 free mg/kg O2(aq); fix a O2(aq)
swap CO2(g) for HCO3-
log f CO2(g) = -3.5; fix f CO2(g)
Na+ = 1 mmolal
Cl- = 1 mmolal
kinetic redox-1 rxn = "CH3COO- + 2 O2(aq) -> 2 HCO3- + H+" \
rate_con = 8e-6 mE = 1 KA = 5e-3
```

Select **Run → Go** to calculate the model.

4.7 Microbial metabolism and growth

React can trace the effect of microbial metabolism and growth in a geochemical system using a generalized kinetic rate law. As described below, the generalized rate law simplifies under specific conditions to each of the rate laws commonly used in microbial ecology.

In **React**, a microbe's metabolism is assumed to be based on the transfer of electrons from a donating half reaction

$$\sum_{\mathsf{D}} v_{\mathsf{D}} \mathsf{D} \iff \sum_{\mathsf{D}^+} v_{\mathsf{D}^+} \mathsf{D}^+ + n \, \mathsf{e}^-$$
(4.33)

to an accepting half reaction

$$\sum_{A^+} v_{A^+} A^+ + n e^- \iff \sum_{A} v_A A$$
(4.34)

Here, D and D⁺ represent species on the reduced and oxidized sides of the donating half reaction, A and A⁺ represent the same for the accepting half reaction, and n is the number of electrons transferred. The microbe's overall metabolic reaction is the sum

$$\sum_{D} v_{D}D + \sum_{A^{+}} v_{A^{+}}A^{+} \iff \sum_{D^{+}} v_{D^{+}}D^{+} + \sum_{A} v_{A}A$$
(4.35)

of the half reactions.

4.7.1 Metabolic rate

React calculates the metabolic rate (mol/s) for the progress of a microbial reaction according to the generalized rate law

$$r_{\vec{k}} = n_w k_+[X]$$

$$\times \frac{\prod_{j} m_{j}^{p_{j}}}{\left(\kappa_{D} \prod_{D^{+}} m_{D^{+}}^{p_{D^{+}}} + \prod_{D} m_{D}^{p_{D}}\right)^{P_{KD}} \left(\kappa_{A} \prod_{A} m_{A}^{p_{A}} + \prod_{A^{+}} m_{A^{+}}^{p_{A^{+}}}\right)^{P_{KA}}} \times TPF$$

$$(4.36)$$

where n_w and [X] are, as before, water mass (kg) and biomass concentration (mg kg⁻¹), k_+ is the rate constant (mol mg⁻¹ s⁻¹), m_j and p_j are the molalities and the powers in the numerator term of the promoting and inhibiting species (which generally appear in the metabolic reaction, although this is not a requirement), P_D and P_A , are the powers in the denominator term for various species in the metabolic reaction, K_D and K_A are the halfsaturation constants for the donating and accepting reactions (varying units, in mol, kg, and s), and P_{KD} and P_{KA} are the overall powers of the K_D and K_A terms.

Variable TPF is the thermodynamic potential factor, given by

$$TPF = \left[1 - \left(\frac{Q}{\kappa}\right)^{\omega} \exp\left(\frac{-\omega n_{\text{ATP}} \Delta G_{\text{ATP}}}{RT_{\kappa}}\right)\right]^{\Omega}$$
(4.37)

where Q and K are the ion activity product and equilibrium constant for the metabolic reaction, and ω and Ω are the rate law orders, as before (see **Nonlinear rate laws**). Variable n_{ATP} is the number of moles of ATP produced per mole of progress of the metabolic reaction, ΔG_{ATP} is the free energy of ATP hydrolysis (the reaction by which adenosine tri-phosphate, ATP, decomposes to adenosine di-phosphate, ADP), R is the gas constant, and T_K is absolute temperature.

The *TPF* is similar to the (1 - Q/K) terms in the other rate laws carried by **React**, except for the exponential term, which accounts for the fact that, to live, the microbe must derive enough energy from its environment to synthesize ATP, the cellular energy store, from ADP.

Note that in contrast to the other types of kinetic reactions, **React** assumes that a microbe's metabolic reaction proceeds only in the forward direction. In other words, the program enforces $r_{\vec{k}} \ge 0$ for all cases.

To construct a microbial model, click add \rightarrow Kinetic \rightarrow Microbial Reaction, set the metabolic reaction in the "reaction" field (or with the rxn or reaction keyword), as before, and specify a rate constant (keyword rate_con) and the reaction orders ω and Ω (order1 and order2). Set the half-saturation constants K_D and K_A for the donating and accepting reactions using the "Kd" and "Ka" fields (or with the KD and KA keywords); by default, these variables take a value of 0.

add delet	e

and selecting a species from the pulldown, or with the mpower (or mpow) keyword, as shown below.

power(CH3COO-)	1.0 • O activity	• molality
add delete		

For the terms in the denominator of the rate law, set the power P_D and P_D^+ of species from the donating reaction by clicking add under "powerD", or using the mpowerD (or mpowD) keyword, and those from the accepting reaction (P_A and P_{A^+}) by clicking add under "powerA", or with mpowerA (or mpowA). You can use the "activity" button or keywords apower, apowerD, or apowerA to set in the rate law a species' activity in place of its molality, as shown below.

power		
power(CH3COO-)	1.0 O molality	
add delete		

Use keywords PKD and PKA to set the exponents P_{KD} and P_{KA} for the grouped terms in the denominator. Keyword ATP_number sets the value of n_{ATP} , and ATP_energy sets ΔG_{ATP} , in kJ/mol.

рКа	1.0]•	рКd	1.0]•
ATP energy	0.0	▼ kJ/mol	ATP number	0.0]•

You set the initial biomass of the microbial population in mg/kg, using the biomass keyword.

initial biomass

•	maka		
	mg/kg		

Over the simulation, **React** determines the rate of change in the biomass [X] from the calculated metabolic rate $r_{\vec{k}}$ according to the relation

$$\frac{d[X]}{dt} = \frac{Y r_{\vec{k}}}{n_w} - D[X]$$
(4.38)

where Y is the growth yield, and D is the decay constant. Specify these parameters in mg mol^{-1} and s^{-1} , respectively, using the growth_yield and decay_con keywords.

growth yield 0.0 reg biomass/mol decay constant 0.0	▼ /sec
---	--------

4.7.2 Relationship to other rate laws

React's microbial rate law reduces under specific conditions to each of the variety of empirical and semi-empirical rate laws commonly applied in microbial ecology. These rate laws include the following equations:

- First-order $\frac{dC}{dt} = k m_D$
- Michaelis-Menten $\frac{dC}{dt} = k \frac{m_D}{K_D + m_D}$
- Zero-order $\frac{dC}{dt} = k$
- Logistic $\frac{dC}{dt} = k [X] m_D$
- Monod $\frac{dC}{dt} = k [X] \frac{m_D}{\kappa_D + m_D}$

• Dual-Monod
$$\frac{dC}{dt} = k [X] \frac{m_D}{K_D + m_D} \frac{m_{A^+}}{K_A + m_{A_+}}$$

• Logarithmic $\frac{dC}{dt} = k [X]$

Here, *C* is the concentration of a product species (or the negative concentration of a substrate of electron accepting species), *k* is a rate constant in appropriate units, [X] is biomass concentration, m_D and m_{A_+} are activities of the limiting reactants in the donating and accepting half reactions, and K_D and K_A are the corresponding half-saturation constants. (The first-order, Michaelis-Menten, logistic, and Monod equations are commonly written in terms of a limiting species from the donating reaction, as shown, but may also be cast in terms of a species from the accepting reaction. In this case, m_{A_+} replaces m_D , and K_A takes the place of K_D in the equations above, as well as in **Table 4.2**).

To invoke one of these laws in **React**, set the appropriate parameters in your input, as shown in **Table 4.2**. In each case, set an appropriate value for the rate constant (keyword rate_con). You can set the rate law order Ω ("order2") to 0,

which negates the thermodynamic potential function and hence casts the laws in the exact form shown above. Alternatively, you can leave Ω at its default value of 1, which will prevent the metabolic reaction in the simulation from proceeding beyond the point of equilibrium, which, of course, is a chemical impossibility.

Table 4.2	empirica should be	Settings for casting microbial rate law in terms of the various empirical equations. Symbol ✓ indicates an appropriate value should be set; x, no value is set. Symbols D and A ⁺ represent name of limiting reactants in donating and accepting half reactions.

4.7.3 Example calculation

As an example, we consider two microbial strains growing by oxidizing acetate (Ac)

$$CH_3COO^- + 2O_2(aq) \rightarrow HCO_3^- + H^+$$
 (4.39)

in a chemostat experiment open to the atmosphere. The microbes' metabolic rate is defined by

$$r_{\vec{k}} = k_{+} [X] \frac{m_{AC}}{\kappa_{D} + m_{AC}} \times \text{TPF}$$
 (4.40)

where the thermodynamic potential factor is

$$TPF = 1 - \left(\frac{Q}{K}\right)^{1/4} \exp\left(-\frac{1/4 n_{\text{ATP}} \Delta G_{\text{ATP}}}{RT_{K}}\right)$$
(4.41)

One of the strains is faster at metabolizing than the other (it has a higher k_+), whereas the second is more efficient (lower k_D). Double-click on file "Microbes.rea" and go to the **Config** \rightarrow **Redox Couples...** dialog.

$\begin{tabular}{ c c c c c } \hline coupled & & & & & & \\ \hline (O-phth)^{-}/HCO_3^{-} & & & & \\ Am^{++++}/Am^{+++} & & & & \\ AmO_2^{+}/Am^{+++} & & & & \\ AsO_4^{-+}/As(OH)_4^{-} & & & & \\ AsO_4^{}/As(OH)_4^{-} & & & & \\ Au^{+++}/Au^{+} & & & \\ CH_4(aa)/HCO_3^{-} & & & \\ ClO_4^{-}/Cl^{-} & & & \\ \hline \end{tabular}$	Redox couples		select with	invert	selection	×

Select **Run** \rightarrow **Go** to calculate the model. In the calculation results, the rapidly metabolizing strain grows fastest initially, but with time is replaced by the more efficient strain.

4.8 Chaining together kinetic paths

You can use the pickup command (see **Picking up the results of a run** in the previous chapter) to chain together kinetic reaction paths. When you pick up the results of a calculation, **React** retains all or some of the kinetic reactions being traced, at their endpoint states. You can then initiate a subsequent simulation that traces continued progress of the kinetic reactions.

In the simplest case, when you pick up the entire system using **Run → Pickup → System → Entire** (or the command pickup),

ξ React								_		×
File Edit	Run	Config	View Help							
Basis		Go	Ctrl+G	ommand	Results					
Step 9 Step 9		Go Initial Kill	Ctrl+I Ctrl+Break	13) 13)						^
Step 9 Step 9		History Pickup	>	ns) System	>	Entire				
Step 9 Step 10 Success		Gtplot	Ctrl+Shift+L	Reactants	>	Fluid				
<				a pacit.						>
	Follow Output Run View Results Plot Results									

ξ React \times File Edit Run Config View Help Go Ctrl+G Results Basis ommand Go Initial Ctrl+I Step 9 s) Kill Ctrl+Break Step 9 hs) Step 9 History... hs) Step 9 Pickup System Entire Step 9 Step 10 Reactants > Fluid Gtplot Ctrl+Shift+L path. Success_ Follow Output Run View Results Plot Results

the program retains whatever kinetic reactions are set. Using **Run** → **Pickup** → **System** → **Fluid** (or pickup fluid),

causes **React** to retain the kinetic reactions occurring within the aqueous phase—the kinetic redox and aqueous complexation reactions—for the new reaction path; kinetic reactions involving minerals, end members, surfaces, a gas phase, or microbes are discarded.

Picking up the entire endpoint system, or just the endpoint minerals, as reactants (i.e., pickup reactants or pickup reactants = minerals) causes the program to retain the kinetic reactions involving precipitation and dissolution of minerals and end members. The pickup reactants = minerals command, then, lets you model experiments in water-rock interactions in which minerals react kinetically with a fluid that is periodically refreshed.

To see how kinetic reactions can be chained together, start by simulating the kinetic dissolution of quartz in dilute water at 100°C:

```
time end = 10 hours
T = 100 C
SiO2(aq) = 1 umol/kg
react 5000 g Quartz
kinetic Quartz rate_con = 2.e-15 surface = 1000
go
```

We wish to figure the effect, after reacting the quartz for 10 hours, of adding a reaction promoter to the solution. To do so, pick up the calculation results, increase the rate constant by a factor of 5 to reflect the promoter, and run a second path.

```
pickup
kinetic Quartz rate_con = 10.e-15
go
```

Over the course of the second reaction path, which begins at t = 10 hours and continues to t = 20 hours, quartz dissolves more rapidly than in the first, reflecting the increased value of the rate constant.

Custom Rate Laws

React's built-in rate laws for mineral and end member dissolution and precipitation, aqueous and surface complex dissociation and association, redox, microbe-mediated reactions, and gas transfer can be applied to the great majority of kinetic problems in geochemistry. For cases in which you wish to apply a rate law of a differing form, however, you can easily define one of your own.

You can define a rate law in any of three ways:

- Specify its form as a character string. For example, you might set rate_con * surface * (1 Q/K) as a rate law.
- 2. Prepare a file that contains a script of commands for calculating the reaction rate. Write the script in a simplified version of the MS Visual BASIC language, as described below.
- 3. Write and compile your own function for evaluating the rate law (you will probably want to use C++), and link it into a library. **React**, as it runs, opens the library and executes the function directly whenever it needs to evaluate the rate law.

Each method is described below.

5.1 Setting the rate law form directly

The simplest method for defining a rate law is to specify its form as a character string. **React** contains an interpreter (prepared with the "Bison" compiler; see **Further Reading**) that converts the character string into computer instructions that **React** executes.

You set the form of the rate law with the rate_law parameter of the kinetic command. For example, you might enter the command

```
kinetic Quartz rate_law = "rate_con * surface * (1 - Q/K)", \
    rate_con = 1e-18, surface = 1000
```

This command will cause the reaction rate for quartz to be calculated as the product of the rate constant, the mineral's surface area, and its saturation.

Table 5.1 lists the parameters, such as rate_con, that you can use to set rate laws in this manner. There are also a number of "helper functions" that you can invoke; these are listed in Table 5.2. For example, in your script you can use the helper function activity ("H+") to denote activity of the hydrogen ion.

In addition to these parameters, a number of parameters identifying the current nodal block and describing its properties are available in **X1t** and **X2t**. For a list of these parameters, see the appendix on **Heterogeneity** in the *GWB Reactive Transport Modeling Guide*.

If you enclose helper function arguments in double quotes ("), you need to delimit the rate law itself with single quotes ('). For example,

kinetic redox-1 rate law = 'Wmass * molality("Na") * rate con'

Alternatively, use single quotes to set off helper function arguments and double quotes for the rate law string.

5.2 Rate law scripts

You can define more sophisticated rate laws by preparing a script in a simplified form of the BASIC language, as described in **Table 5.3**. Save the script in a file, the name of which must end with the extension .bas. You then specify the file's name in the kinetic command with the rate law parameter. For example, the command

```
kinetic Quartz rate law = My script.bas rate constant = 10^-16
```

tells **React** that the rate law for the reaction of Quartz is to be found in the specified file. You also use the kinetic command in the usual way to set any parameters used by your script, such as the rate constant or specific surface area, as shown above. **React** looks for your .bas file first in the current working directory, and then in the directory where the GWB is installed (for example, C:\Program Files\GWB). You can, of course, specify a full path name to the file, to avoid ambiguity.

Alternatively, you can set your rate law script directly within your input file. For example, the input

```
kinetic Quartz rate_law = {
   rate = Wmass * rate_con / activity("H+")
   RETURN rate
}
```

sets the rate law script directly, without need to refer to an external file.

Your script can access the parameters in **Table 5.1**, as well as the "helper functions" in **Table 5.2**. Parameters in rate law scripts are copies of the values carried internally by **React**; with four exceptions, these values cannot be changed from your script. The exceptions are the biomass, the two kinetic factors in the microbial model, and the thermodynamic potential factor (parameters "biomass", "FD", "FA", and "TPF"), which you can set with the special function setgwbvar. For example, the entry

```
setgwbvar("biomass", newbiom)
```

sets the current value carried by **React** for "biomass" to the value of "newbiom", previously calculated in the script.

An example of a rate law script (the example scripts in this section are found in files within the "src" subdirectory, where the GWB is installed) is

```
IF QoverK < 1 THEN 20 ELSE 40
20: rate = rate_con * surface * (1 - Q/K)
GOTO 60
40: rate = 0.0
60: RETURN rate</pre>
```

In this example, the dissolution rate of a mineral is calculated from its rate constant, surface area, and saturation. The mineral's rate of precipitation, should it appear supersaturated, however, is 0.

As a second example, we account in the rate law script for the effects of promoting and inhibiting species on a mineral's reaction rate.

```
cat = 1.0
i = 1
begin_loop: IF i > ncatal THEN GOTO end_loop
   cat = cat * acatal(i)^pcatal(i)
    i = i + 1
GOTO begin_loop
end_loop: rate = cat * rate_con * surface * (1.0 - QoverK)
RETURN rate
```

Similarly, we could write a script to return the rate of a redox reaction in the form

```
cat = 1.0
i = 1
begin_loop: IF i > ncatal THEN GOTO end_loop
   cat = cat * acatal(i)^pcatal(i)
    i = i + 1
GOTO begin_loop
end_loop: rate = Wmass * cat * rate_con * (1.0 - QoverK)
RETURN rate
```

As a final example, we construct a script to return the rate of microbial metabolism, taking Ω to be unity. In this case, we need to calculate how the microbial biomass and the thermodynamic potential factor vary, and update each in **React**'s memory space using the setgwbvar function, as described above.

```
aff = QoverK * exp(-ATP number * ATP energy / (8.3143 * TK))
aff = aff^order1
IF (aff > 1.0) THEN aff=1.0
prod = 1.0
i=1
begin_loop1: IF i>ncatal THEN GOTO end_loop1
  prod = prod * acatal(i)^pcatal(i)
   i=i+1
GOTO begin loop1
end loop1:
prodKd1 = KD
prodKd2 = 1.0
i=1
begin loop2: IF i>nspecD THEN GOTO end loop2
  IF signD(i) > 0 THEN prodKd1 = prodKd1*actD(i)^powerD(i)
  IF signD(i) < 0 THEN prodKd2 = prodKd2*actD(i)^powerD(i)</pre>
   i=i+1
GOTO begin loop2
end loop2:
```

```
(cont'd)
prodKal = KA
prodKa2 = 1.0
i=1
begin loop3: IF i>nspecA THEN GOTO end loop3
   IF signA(i) > 0 THEN prodKal = prodKal*actA(i)^powerA(i)
   IF signA(i) < 0 THEN prodKa2 = prodKa2*actA(i)^powerA(i)</pre>
   i=i+1
GOTO begin loop3
end loop3:
tpf = 1.0 - aff
fd = prodKd2 / (prodKd1 + prodKd2)^PKD
fa = prodKa2 / (prodKa1 + prodKa2)^PKA
setgwbvar("TPF", tpf)
setgwbvar("FD", fd)
setgwbvar("FA", fa)
denom = (prodKd1 + prodKd2)^PKD * (prodKa1 + prodKa2)^PKA
rprime = rate con * (prod/denom) * tpf
IF (Deltat <= 0.0) THEN GOTO end block
  rprime0 = dndt0/(biomass0 * Wmass)
  rpave = (1.0-Theta)*rprime0 + Theta*rprime
  biom = biomass0*exp((growth yield*rpave-decay con)*Deltat)
  IF biom < 0.0 THEN biom = 0.0
   setgwbvar("biomass", biom)
end block:
return rprime * biomass * Wmass
```

Note the technique used in this script to update the biomass. The time rate of change in biomass concentration is given as

$$\frac{d[X]}{dt} = \frac{Yr_{\vec{k}}}{n_w} - D[X]$$
(5.1)

as described in the previous section of this guide. We can re-express this relation in integral form to give biomass concentration [X] at the end of a reaction step

$$[X] = [X]_0 e^{(Y_t' - D)\Delta t}$$
(5.2)

from the concentration $[X]_0$ at the beginning of the step, the reaction rate r' per unit biomass concentration per kg water (where $r_{\vec{k}} = r' n_w[X]$), and the step length Δt .

5.3 Compiled rate laws

If you have a little interest in programming, you may wish to write your own rate law function, most likely in C++. **React**, as it runs, can link to your function and call it directly. This method provides the most efficient and powerful way to define a custom rate law.

There are three steps in the procedure:

- Write a function that returns the reaction rate (and optionally its derivatives) for a kinetic reactant, using the "gwb_context.h" and "ratelaw_param.h" header files supplied with the GWB software release. Copies of these files are found in the "src" subdirectory, where the GWB is installed.
- 2. Compile the function and link it into a dynamic link library (or DLL). The DLL must end in the extension .dll. You may link, within a single library, one or several rate law functions.
- In the React input, specify the names of the library and function, separated by a colon (:). For example, setting

kinetic Quartz rate law = my lib.dll:my ratelaw

Each rate law function takes three parameters:

- An integer value *i*. When *i* is -1, the function should calculate reaction rate, returning a value in mol/sec. When *i* is the index of a basis entry (i.e., it is in the range 0 to the number of basis entries, less 1), the function should calculate the derivative of reaction rate with respect to the indicated basis entry. Alternatively, the function may return the special value "ANULL", in which case **React** will calculate the derivative itself, using finite differences.
- 2. Reference to a "Reactant" data structure that describes the kinetic reaction in question. This reference should be named "r". The form of this data structure is defined in a header file "gwb_context.h", which is distributed with the GWB.
- 3. Reference to a "GWBcontext" data structure that contains information about current conditions (temperature, ionic strength, and so on) in the **React** simulation. This reference is named "c". Again, the form of this data structure is defined in "gwb_context.h".

The parameters in **Table 5.1** are available to your function. These parameters are defined in a second header file "ratelaw_param.h", which should be included at the top of the function. You can also use as parameters any of the entries in the "GWBcontext" data structure, as set out in "gwb_context.h". In addition, the "helper functions" listed in **Table 5.2** are available. To debug functions, use the printf function (but not cout) to display data.

As an example of a rate law function, consider a mineral that dissolves according to its rate constant, surface area, and saturation, but does not precipitate. Such a function, here named "example1", can be written

```
#define EXPORT extern "C" __declspec(dllexport)
#include <windows.h>
#include <stdio.h>
#include <math.h>
#include "gwb_context.h"

EXPORT double example1(int i, Reactant &r, GWBcontext &c)
{
    #include "ratelaw_param.h"
    if (QoverK > 1.0) // Mineral does not precipitate.
        return 0.0;
    else if (-1 == i) // Dissolution rate.
        return rate_con * surface * (1.0 - QoverK);
    else // Let React determine derivatives.
        return ANULL;
}
```

Note the need to export the function from the DLL. We specify a C rather than C++ function, to avoid "name globbing" conflicts among compilers. Also note that by returning "ANULL" when **React** requests a derivative, we tell **React** to compute these values itself, using finite differences.

To compile the DLL, open your compiler's 64-bit command line environment corresponding if you have 64-bit GWB version installed on your computer, or the 32-bit environment if you are running 32-bit GWB. The commands

```
cl /MD /02 /c example1.cpp
link /dll example1.obj react.lib /out:mylib.dll
```

compile and link this function using the Microsoft C++ compiler, and

```
icl /MD /02 /c example1.cpp
xilink /dll example1.obj react.lib /out:mylib.dll
```

do the same for the Intel C++ compiler. Here, file "example1.cpp" contains the C++ source, and "react.lib" is a short dataset supplied with the GWB; parallel files "x1t.lib" and "x2t.lib" are supplied for use with programs **X1t** and **X2t**.

Note you should change to a working directory in your file space before compiling and linking; the process will not work correctly in a system directory, such as \Program Files.

It is important to note that the internal data structures in the GWB will likely change as the software continues to evolve. You should preserve the source code for your rate law functions, so that you can recompile it for future software releases.

As a second example, we consider the same rate law, but instead of allowing **React** to compute the derivatives by finite differences, which can be time consuming, we calculate them directly. The forms of the derivatives are given in the *Geochemical and Biogeochemical Reaction Modeling* text (see **Further Reading**). The code (omitting the global headers) is:

```
EXPORT double example2(int i, Reactant &r, GWBcontext &c)
{
    #include "ratelaw_param.h"
    if (QoverK > 1.0)
        return 0.0;
    else if (-1 == i)
        return rate_con * surface * (1.0 - QoverK);
    else if (H2O == i) // Derivative wrt water mass = zero.
        return 0.0;
    else if (i > H2O && i < c.Nbasis) // Other derivatives.
        return -rate_con * surface * mtcoef[i] * QoverK /
Bas[i].c;
    else
        return 0.0;
}</pre>
```

As a third example, we code a rate law that includes promoting and inhibiting species.

```
EXPORT double example3(int i, Reactant &r, GWBcontext &c)
{
    #include "ratelaw_param.h"
    if (-1 == i) {
        double cat = 1.0;
        for (int j=0; j<ncatal; j++)
            cat *= pow(acatal[j], pcatal[j]);
        return cat * rate_con * surface * (1.0 - QoverK);
    }
    else
        return ANULL;
}</pre>
```

We consider in a fourth example how we might represent the rate law for a redox reaction.

```
EXPORT double example4(int i, Reactant &r, GWBcontext &c)
{
    #include "ratelaw_param.h"
    if (-1 == i) {
        double cat = 1.0;
        for (int j=0; j<ncatal; j++)
            cat *= pow(acatal[j], pcatal[j]);
        return Wmass * cat * rate_con * (1.0 - QoverK);
    }
    else
        return ANULL;
}</pre>
```

In a final example, we write a function to calculate the rate of microbial metabolism, taking Ω to be unity. Note that, in this case, if we are to account for growth, we must update the microbial biomass (variable biomass); we also calculate the kinetic factors "FD" and "FA", as well as the thermodynamic potential factor "TPF", so they will be available in the program output.

```
EXPORT double example5(int i, Reactant &r, GWBcontext &c)
{
   #include "ratelaw param.h"
   double aff, rpave, rprime, rprime0;
   double prod, prodKd1, prodKd2, prodKa1, prodKa2;
   if (-1 == i) {
      aff = QoverK * exp(-ATP number*ATP energy/ (8.3143*TK));
      aff = pow(aff, order1);
      aff = min(aff, 1.0);
      prod = 1.0;
      for (int j=0; j<ncatal; j++)</pre>
         prod *= pow(acatal[j], pcatal[j]);
      prodKd1 = KD;
      prodKd2 = 1.0;
      for (int j=0; j<nspecD; j++)</pre>
         if (signD[j] > 0)
            prodKd1 *= pow(actD[j], powerD[j]);
         else if (signD[j] < 0)
            prodKd2 *= pow(actD[j], powerD[j]);
      prodKa1 = KA;
      prodKa2 = 1.0;
      for (int j=0; j<nspecA; j++)</pre>
         if (signA[j] > 0)
            prodKa1 *= pow(actA[j], powerA[j]);
         else if (signA[j] < 0)</pre>
            prodKa2 *= pow(actA[j], powerA[j]);
      TPF = 1.0 - aff;
      FD = nspecD > 0 ?
         prodKd2 / pow(prodKd1 + prodKd2, PKD) : ANULL;
      FA = nspecA > 0 ?
         prodKa2 / pow(prodKa1 + prodKa2, PKA) : ANULL;
      rprime = rate con * (prod /
         (pow(prodKd1 + prodKd2, PKD) *
          pow(prodKa1 + prodKa2, PKA))) * TPF;
      if (Deltat > 0.0) {
         rprime0 = dndt0 / (biomass0 * Wmass);
         rpave = (1.0 - Theta) * rprime0 + Theta * rprime;
         biomass = biomass0 * exp((growth yield * rpave -
            decay con) * Deltat);
         biomass = max(biomass, 0.0);
      }
```

```
(cont'd)
    return rprime * biomass * Wmass;
  }
  else
    return ANULL;
}
```

The technique for updating biomass here is described in the previous topic, **Rate law** scripts.

Table 5.1	Internal param sensitive.	neters for defining rate laws. Parameters are case
Parameter		Meaning
Chemical cor	oditions	
рН		pН
logfO2		Log di-oxygen fugacity
Eh		Redox potential (V)
ре		ре
TDS		Dissolved solids (mg/kg)
IS		Ionic strength (molal)
SIS		Stoichiometric Ionic strength (molal)
chlorinity		Chlorinity (molal)
Watact		Water activity
soln_density		Solution density (g/cm ³)
soln_viscosit	У	Solution viscosity (cp)
alkalinity		Water alkalinity (mg/kg as CaCO ₃)
EC		Electrical conductivity (uS/cm)
hardness		Total hardness (mg/kg as CaCO₃)
hardness_ca	rb	Carbonate hardness (mg/kg as CaCO ₃)
hardness_nc	arb	Non-carbonate hardness (mg/kg as CaCO ₃)

Phases	
Wmass soln_mass rock_mass soln_volume rock_volume	Mass of solvent water (kg) Mass of fluid in nodal block (kg) Mass of minerals in nodal block (kg) Volume of fluid in nodal block (cm ³) Volume of minerals in nodal block (cm ³)
Reactant properties	
name rxn, reaction mw mv order1 order2	Reactant name Kinetic reaction, as a character string Mole weight of a kinetic mineral (g/mol) Mole volume of a kinetic mineral (cm ³ /mol) Rate law order ω for Q/K term Rate law order Ω for (1 – Q/K) term
ncatal catal (1), catal (2), pcatal (1), pcatal (2),	Number of promoting and inhibiting species in rate law Names of promoting and inhibiting species Powers (exponents) of promoting and inhibiting species
xaffin catalyst enzyme KA	Name of cross-affinity mineral Name of catalyst Name of enzyme Half saturation constant <i>K</i> ^A for forward reaction in enzyme model, and electron accepting reaction in microbial model
KD KP	Half saturation constant K_P for electron donating reaction in microbial model Half saturation constant K_P for reverse reaction, enzyme model
nspecD	Number of species in " K_D " product functions in the microbial model
specD(1), specD(2), powerD(1), powerD(2), signD(1), signD(2), nspecA	Names of species in " K_D " products Powers (exponents) of species in " K_D " products Signs (+ for right side of reaction, - for left) of reaction coefficients for species in " K_D " products Number of species in " K_A " product functions in the

	microbial model

freeflowing, Vfree	Volume of free-flowing zone in block (cm ³)
stagnant, Vstag	Volume of stagnant zone in block (cm ³)
Xarea	Area (cm ²) of nodal block normal to x direction
Yarea	Area (cm ²) of nodal block normal to y direction
Poros0	Sediment initial porosity, as a fraction
porosity	Sediment porosity, as a fraction
Time marching	
Time	Time (s)
Tstart	Starting time (s)
Tend	Ending time (s)
Deltat	Length of time step (s)
Theta	Time weighting variable
Xi	Reaction progress
PV	Pore volumes displaced

Table 5.2	"Helper functions" available in rate law scripts. Each function takes a character variable or string as an argument and returns a numeric value. Function names are case sensitive.				
"Helper function"		Returns			
activity(specie	es)	Activity of a species or end member (or fugacity of a gas)			
fugacity(<i>gas</i>)		Fugacity of a gas			
gamma(<i>species</i>)		Activity coefficient of a species or end member			
boltzman (surfa	ce species)	Boltzman factor for a surface species			
molality(specie	es)	Molal concentration of a free species			
xss(species)		Mole fraction of an end member			
gas_pressure	(gas)	Partial pressure of a gas (bar)			
mass(<i>species</i>)		Mass of a species, mineral, end member, or reactant (mol)			
totmolal(<i>basis entry</i>)		Molal concentration of a component (a basis entry, before swapping) in the fluid			
totmoles(basis	<i>entry</i>)	Moles of a component in the fluid			
totmoles_rck((basis entry)	Moles of a component in the rock (minerals and end members)			
totmoles_sys((basis entry)	Moles of a component in the system			
totmoles_sor((basis entry)	Moles of a component in the sorbate			
totmoles_col((basis entry)	Moles of a component in mobile colloids			
totmoles_stg	(basis entry)	Moles of a component in the stagnant zone			
QovK (reactant)		<i>Q/K</i> for a mineral, solid solution, or kinetic reaction			
logQovK(<i>reactar</i>	nt)	Affinity of a mineral, solid solution, or kinetic reaction			
reaction_rate	e(<i>reactant</i>)	Rate of a mineral or kinetic reaction (mol/s)			

<pre>surf_charge(surface type) or surf_charge0(surface type)</pre>	Electrical charge at the 0-plane (C/m²) of a sorbing surface
surf_chargeb(<i>surface type</i>)	Electrical charge at the β -plane (C/m ²)
<pre>surf_charged(surface type)</pre>	Electrical charge at the <i>d</i> -plane (C/m ²)
<pre>surf_potential(surface_type) or surf_potential0(surface_type)</pre>	Electrical potential at the 0-plane of a sorbing surface (V)
<pre>surf_potentialb(surface_type)</pre>	Electrical potential at the β -plane (V)
<pre>surf_potentiald(surface_type)</pre>	Electrical potential at the <i>d</i> -plane (V)
sorb_area(<i>surface_type</i>)	Area of a sorbing surface (m ²)
Eh(<i>redox couple</i>)	Redox potential of a redox couple (V)
mw(species)	Mole weight of a species or reactant (g/mol)
mv(species)	Mole volume, mineral or reactant (cm³/mol)
species_index(<i>species</i>)	Index in program arrays of aqueous species
mineral_index(<i>species</i>)	Index of a mineral species
<pre>ssoln_index(solid solution)</pre>	Index of a solid solution
gas_index(<i>species</i>)	Index of a gas species
<pre>surf_index(species)</pre>	Index of a surface species
<pre>surftype_index(surface type)</pre>	Index of a surface type
<pre>reactant_index(reactant)</pre>	Index of a reactant
couple_index (<i>couple</i>)	Index of a redox couple

Table 5.3Summary of synsensitive.	Summary of syntax for rate law scripts. Keywords are not case sensitive.				
LET variable = expression	Assignment of a numerical value or character string. The LET is optional. Variable names start with a letter and may contain digits and underscore characters				
label: statement	Statement label, may be numeric or a character string				
statement : statement	A colon (:) separates statements on a single line				
goto <i>label</i>	Begin executing statements following label. GOTO and GO_TO are synonymous. The label may be a number or a character string Examples: GOTO 100 GOTO Line1				
IF condition THEN statement or label ELSE statement or label	Conditional execution; the ELSE clause is optional. The condition is false if it evaluates to 0, otherwise true. Example (appears on one line): IF x > 0 THEN 20 ELSE PRINT "too small"				
REM comment	A remark. Any characters until the end of the line are ignored.				
+, -, *, /, ^, MOD	Arithmetic operations, including exponentiation. Example: $x + y$				
	Negation: - y				
=, <, >, <=, >=, <>	Comparisons of numeric or character values, such as x < y Comparison of character strings is case- insensitive				
AND, OR, XOR, NOT	Logical operators. Each except NOT takes two operands, such as $x \ \ AND \ \ y$				
PI	Value of π (3.14159)				

(expression)	Grouping and association: $x \ * \ (y \ + \ z)$
ABS, EXP, LN, LOG10, SQRT, SGN	Absolute value, exponentiation, natural and common logarithms, square root, and sign functions. EXP (x) is e^x
SIN, COS, TAN, ASIN, ACOS, ATAN, SINH, COSH, TANH	Trigonometric functions (taking values in radians), their inverses, and hyperbolic trig functions
MIN, MAX	Minimum or maximum of two values
DIM var1 (dimension), var2 (dimension)	Declare and allocate memory for one or more arrays. In the example: DIM A (3) Array A has entries A (1), A (2), and A (3). Arrays may contain up to 1000 entries.
PRINT <i>item1, item2</i>	Print the numerical values or character strings in a list of items. Items are separated by commas, or by semicolons, in which case the corresponding values appear without an intervening space. Example: PRINT "rate_constant =", rate_con
PAUSE <i>item1, item2</i>	Print any items listed and pause execution until the user touches a key. Syntax is the same as for the PRINT command
RETURN <i>expression</i>	Terminate the program and return the value of "expression"
END	Terminates the script. This statement is not required.

Using Gtplot

Gtplot is an interactive, mouse-driven program that produces various types of diagrams showing the results of tracing reaction paths with **React**.

After tracing a reaction path with **React**, start **Gtplot** by clicking on **Plot Results** on the **Results** pane, or selecting **Run** \rightarrow **Gtplot** from **React**'s menubar. The program will read the calculation results from the ".gtp" file **React** produced and render them graphically. You can leave **Gtplot** active when you run further **React** simulations. Each time **React** completes a run, it signals **Gtplot**, which updates its display to reflect the new results.

You can also start **Gtplot** by opening any ".gtp" or ".gtc" file, or by clicking on the **Gtplot** icon on the Apps pane of the GWB dashboard. You can take input from a different dataset by choosing **File** \rightarrow **Open** \rightarrow **Data File...** from the menubar.

6.1 Initial plot

Gtplot opens a window on your screen, reads input data from a ".gtp" file, and renders the data as a two-dimensional plot. The window has three parts: a graphics area, a menubar with pulldown menus, and a frame showing the name of the input dataset and its activity model.

The initial plot shows how bulk fluid composition in the **React** calculation, expressed in terms of thermodynamic components, varies with reaction progress ξ . The program, however, can make different kinds of plots that show the following types of variables:

- Mass and volume of minerals and end members in the modeled system
- Concentration, activity, and activity coefficients of dissolved species
- Elemental composition of the fluid, minerals, sorbate, and the bulk system
- Composition of the fluid, minerals, sorbate, and the bulk system, expressed in terms of thermodynamic components
- Gas fugacity and partial pressure
- Saturation indices Q/K with respect to various minerals and solid solutions
- Bulk stable isotopic composition of the fluid, minerals, sorbate, and the entire system, as well as the composition of individual species, gases, and minerals
- Fraction of various components sorbed onto mineral surfaces
- Variables such as temperature, pH, and reacted mass

In addition, you can plot the results of the **React** calculation on any of the special plot types, such as Piper and Durov diagrams (see **Using Gtplot** in the *GWB Essentials Guide*). Use the **Plot** menu to control the type of plot produced and the configuration of the plot.

Gtplot works using information about the system modeled, including its bulk composition (i.e., its composition in terms of Na⁺, Ca⁺⁺, and so on), and the fluid's pH, TDS, carbonate speciation, and so on. Some of the "special" plots show variables labeled "HCO₃ + CO₃". Such plots show the sum of the concentrations in solution, in terms of electrical equivalents per kg fluid, of the free HCO₃ and CO₃ species. The program calculates this sum from the fluid's carbonate alkalinity, as determined by the **React** program. Hence, the value shown for the variable depends not only on carbonate concentration, but the fluid's pH. In contrast, plots labeled "HCO3" represent the bulk carbonate concentration of the fluid, taking no account of the speciation of carbonate to the CO₃, HCO₃, and CO₂(aq) species.

When **Gtplot** starts for the first time in a given directory, it assumes a default configuration. Upon finishing, the program saves for its next run a dataset containing the current configuration of the plots. You can select options from the **File** menu to specify an alternative configuration (see **Loading and saving plot configuration**) or reset the entire program configuration.

6.2 XY Plot configuration

Choose **Plot** \rightarrow **XY Plot**... to specify the configuration of the xy plot. Alternatively, you can alter the configuration by interacting with the graphical aspects of the plot, such as any data line, data label, axis, tick mark, label, or grid line. A **right-click** on an aspect of the plot displays a menu showing the options available. **Double-click** on an aspect to invoke the **XY Plot Configuration** dialog. Dragging an inner or outermost axis tick mark, number,

or grid line will shift or scale, respectively, the axis range, (see **Using Gtplot** in the **GWB** *Essentials Guide*).

The **X** Axis and **Y** Axis tabs let you select one variable to plot on the x axis, and one or more variables to plot on the y axis. Use **Variable type** to control the type of variables to appear along the plot's axes. Variable type options are:

- Chemical parameters such as temperature, pH, and mass solution
- Physical parameters such as fluid density, porosity, and fluid velocity
- Reactant properties such as net reaction progress and reaction rates
- Components in the fluid, minerals, sorbate, and the bulk system (fluid plus sorbate and rock)
- Component Kd's of the various components that may be sorbed onto mineral surfaces
- Sorbed Fractions of the various components that may be sorbed onto mineral surfaces
- Surface parameters such as charge density, potential, and sorbing surface area
- Species to plot either the concentration, activity, or activity coefficient of one or more aqueous species
- Minerals to represent the masses or volumes of minerals and solid solution end members over the reaction path
- Mineral Saturation to plot the saturation indices (Q/K) of the fluid with respect to one or more minerals, as well as any solid solutions considered
- Gas partial pressure and Gas fugacity of one or more gases in the fluid
- Elemental Composition of the fluid, the rock, the sorbate (i.e., surface complexes), or the system (fluid plus sorbate and rock)
- Isotopic composition of the bulk fluid, rock, sorbate, and system, as well as individual species, for active isotope systems

Use the **Filter** menu to set, for species or mineral saturation plots, a basis species to consider. In a typical reaction path calculation, so many dissolved species are considered, and saturation states are determined for so many minerals, that the data fit poorly on a single plot. For this reason, **Gtplot** can group species and minerals into sets of just those that contain a given basis species. You can choose to plot, for example, the species containing Na⁺, or the saturation indices of minerals containing Al⁺⁺⁺. Alternatively, you may choose to consider all species and minerals.

The selection of a variable type displays a list of possible variables. Click on a variable you wish to select. Use **Ctrl+click** to select multiple variables. Use **Shift+click** to select a range of variables.

Use the following to specify the way the variables are plotted:

- **Variable type** to control the type of variables to appear along the plot's axis.
- **Filter** to list, for species or mineral saturation plots, the set of just those that contain a given basis species.

- Auto-scale to set the data range for the axis to span the data to be plotted.
- Minimum, Maximum, and Tick increment to set the data range for the axis.
- **Reverse axis** to reverse the sense of the axis.
- **Units** to select alternative units, if any, for the axis.
- **As** to plot values as elemental equivalents, or as protonated or deprotonated species equivalents.
- **Type** to set the axis to a linear, log, or delta scale. A delta scale shows change in a variable's value from the initial point in the reaction path.
- First, Previous, Next, and Last to cycle through the variable choices.

	Chemical parameters		\sim	Variable type Comp	oonents in fluid			`
	Chemical parameters Physical parameters			Filter				
Temperature Mass H20 Mass solution Dissolved soli pH f 02(g) Eh Pe Ionic strength Chlorinity m Cl-		cients		H20 Al+++ CI- H+ HCO3- K+ Mg++ Na+ SO4 SiO2(aq)				irst vious ext ast ect all
🗹 Auto-scale	Reverse axis			Auto-scale	Reverse axis			
Minimum	-5	÷V	~	Minimum	0	*	mmolal	
	5	*		Maximum	.9	*	as K+	
Maximum								

6.3 Plot types

In addition to using the xy plot, you can plot the results of the **React** calculation on any of the special plot types, including as a ternary diagram, Piper diagram, Durov diagram, Schoeller diagram, Stiff diagram, radial plot, bar chart, and pie chart. Use the **Plot** menu to control the type of plot produced and the configuration of the plot. Each selection invokes a dialog box specific to the type of plot in question (see **Using Gtplot** in the **GWB Essentials Guide**).

6.4 Editing plot appearance

Gtplot allows you to interactively modify many aspects of the diagram. The details of using active items, aspect menus, and dialogs to edit the plot appearance are given in the **Using Gtplot** section of the **GWB Essentials Guide**.

6.5 Scatter data

Gtplot can overlay the data in a **GSS** data sheet (a .gss file) as "scatter data" on a plot of the results of a **React** calculation. The program can add scatter data to any of the plots it makes, except bar and pie charts. To coordinate the plotting of sample dates and times in the **GSS** data sheet on the reaction path, set an explicit starting date and time in **React**. To read a .gss file into **Gtplot**, select **File** \rightarrow **Open** \rightarrow **Scatter Data...** Clear scatter data from a diagram on the **Open** \rightarrow **Scatter Data...** dialog, with the **OFF** button.

The **Scatter data** section of the **Using Gtplot** chapter in the *GWB Essentials Guide* gives details on plotting scatter data from .gss files.

In GWB releases 7.0 and earlier, the program took scatter data from a specially formatted text file, rather than a .gss data sheet. Legacy scatter files are still supported, and are described in the **Scatter Data** chapter in the **GWB Reference Manual**.

6.6 Loading and saving plot configuration

Upon finishing, **Gtplot** writes into the user's working directory a file, "gtplot_conf.gtc", containing the configuration of the current plots. When the program starts again in the same directory, it reads the file and assumes the same configurations.

Choosing File → Reset Configuration or the reset option from the command line (see Gtplot command line) returns the configuration for each plot type to its default state.

You can also save plot settings in ".gtc" configuration files. To do so, select **File** \rightarrow **Save As...** You can then specify that file as the configuration for a later **Gtplot** run from the command line (the -c flag; see **Gtplot command line**) or read it into **Gtplot** by selecting **File** \rightarrow **Open** \rightarrow **Configuration...**

Exiting the program by choosing **File** → **Abort (No Save)** causes an immediate exit from the program; the plot configuration is lost.

6.7 Exporting the plot

Gtplot makes it convenient to use the plots you create in articles, reports, presentations, and databases. You can copy the current plot to the clipboard and then paste it into a variety of applications, in a format meaningful to the application.

To copy a plot, use **Edit** \rightarrow **Copy** or **Ctrl+C**. If you paste the plot into MS PowerPoint, it will appear as an EMF (an MS Enhanced Metafile) graphic object. Pasting into Adobe Illustrator places a native AI graphic.

If you paste the plot into MS Excel or a text editor, such as Notepad or MS Word, the numerical values of the data points that make up the lines on the plot will appear in spreadsheet format.

You can control the format in which the plot is copied to the clipboard by selecting **Edit** \rightarrow **Copy As**. You can choose to copy the plot as an AI object, an EMF object, or a bitmap, or to copy the data points in the plot as tab delimited or space delimited text. Use the tab delimited option to paste the data into a spreadsheet program like MS Excel. For examining the data in a text file created with an editor like Notepad or MS Word, copying from **Gtplot** using the space delimited option and then pasting into the editor writes a nicely aligned table.

Paste "Paste" in Excel or Word inserts numerical values Σ ⋅ ½7 ⋅ □ 2 ⋅ 2 ⋅									۵ (
-	e Options:				£		Edit	ing	
Α					f _*				
	Use Text Imp	ort Wizard		et.xlsx			_		23
	Paste <u>S</u> pecia	il		С	D		E	F	=
1	X position	Calcite	Као	linite	Quartz	Be	idellit-C	a	
2	cm	mol/cm3	mol	/cm3	mol/cm	3 m	ol/cm3		_
3	34.48	0.001354	0.0	00502	0.022	04	0		
4	103.4	0.001354	0.0	00502	0.022	04	0		
5	172.4	0.001354	0.0	00502	0.022	04	0		
6	241.4	0.001354	0.0	00502	0.022	04	0		
7	310.3	0.001354	0.0	00502	0.022	04	0		
8	379.3	0.001354	0.0	00502	0.022	04	0		
9	448.3	0.001354	0.0	00502	0.022	04	0		
10	517.2	0.001354	0.0	00502	0.022	04	0		
11 4 4		0.001354 eet1 She		00502 / She	0.022 et3 ्1 ◀	n4	0		▼ 1.:i

In MS Word or MS Excel, use **Paste Special...** to paste the plot as a picture instead.

Use File → Save Image... to copy the plot, in your choice of formats (selected under Save as type:), from the graphics area to a file in the specified directory. The Enhanced Metafile option, for example, saves the plot image in a format that can be read by most art and illustration programs (see Graphics Output in the GWB Reference Manual). The other file formats available are: PNG, JPEG, TIFF, Bitmap, Adobe Illustrator, PDF, Scalable Vector Graphics, Compressed SVG, Encapsulated PostScript, Color PostScript, and B/W PostScript.

When saving a PNG, JPEG, TIFF, or bitmap file, you may specify the quality of the saved image by choosing its resolution: High, Medium, Low, or Custom. Use **Custom...** to set the pixel width and height of the image, and to choose whether to preserve the aspect ratio of the plot. Use the **Spreadsheet File (Tab delimited)** or **Text File (Space delimited)** option to save the numerical coordinates of the data points on the plot as a table. The spreadsheet table can be read directly into many popular spreadsheet programs.

Certain graphics types support font embedding. PDF files should always display and print properly, regardless of fonts installed on the system. PostScript files should also, if you have used the option to embed fonts. If you may want to edit the PostScript file, however, you should deselect the option to embed fonts, because programs such as Adobe Illustrator may restrict your ability to edit a document using embedded fonts. To edit these files, be sure that all of the required fonts are installed on your computer (see **Font for data markers** in the *GWB Reference Manual*).

When importing AI graphics to Adobe Illustrator, the program may prompt you to update the legacy text before you can edit the file. In this case, choose "Update". You need to release the clipping mask before you attempt to edit individual elements of the plot. Use the "Ungroup" and "Group" functions when repositioning or modifying elements.

6.8 Gtplot command line

To run **Gtplot**, click on the **Gtplot** icon on the GWB dashboard, or open a ".gtp" or ".gtc" file. The program can also be initiated from the Windows command prompt by typing gtplot.exe. Starting the program in this way allows you to make use of the command line arguments described below.

Gtplot accepts a number of arguments from the command line. For example, the command

gtplot -i React plot1.gtp -c Config1.gtc

causes **Gtplot** to read as input the file "React_plot1.gtp", and to use the plot configuration stored in "Config1.gtc".

<input_data> -i <input_data></input_data></input_data>	Set the "React_plot.gtp" dataset, produced by a React run, which contains the data to be plotted.
	The program, by default, looks for file
	React_plot.gtp in the user's working directory.
-c <config_file></config_file>	Set the configuration file to be read at startup. By default, the program reads the file gtplot_conf.gtc if it exists in the working directory.
-scat <scatter_file></scatter_file>	Take scatter data from the named dataset. By default, Gtplot does not plot scatter data.
-graph <plot_type></plot_type>	Set the type of plot displayed at startup. By default, it is set from the configuration file. Choose from: xyplot, ternary, piper, durov, schoeller, stiff, radial, bar, pie, series, and time.
-reset	Set the default configuration at startup; do not read gtplot_conf.gtc.

The following options are available from the command line:

Table 6.1	Keyboard shortcuts in Gtplot
Ctrl+Shift+A	Copy plot to the clipboard as Adobe Illustrator AI file
Ctrl+Shift+B	Copy plot to the clipboard as a bitmap
Ctrl+C	Copy plot to the clipboard
Ctrl+Shift+E	Copy plot to the clipboard as an Enhanced Metafile
Ctrl+F	Refresh display
Ctrl+Shift+G	Get scatter data
Ctrl+L	Load a configuration file
Ctrl+M	Save the graphic image to a file
Ctrl+O	Open an input ("React_plot.gtp") file
Ctrl+P	Print the plot
Ctrl+Q	Quit Gtplot, save configuration
Ctrl+Shift+Q	Abort Gtplot, do not save configuration
Ctrl+R	Reset the plot configuration
Ctrl+S	Save the current configuration to a file
Ctrl+Shift+S	Copy plot to the clipboard as Spreadsheet (tab delimited)
Ctrl+Shift+T	Copy plot to the clipboard as Text (space delimited)
Ctrl+U	Update the plot from the current input file
Ctrl+X	Reset data range on the x axis
Ctrl+Y	Reset data range on the y axis
Ctrl+Z	Reset data ranges on the x and y axes
F1	Open GWB Reaction Modeling Guide

Phase2, as described in the **Introduction** to this guide, is a program designed for calculating a broad variety of two-dimensional diagrams for geochemical systems. The program works by tracing a stacked series of reaction paths that traverse the plot axes, then assembling the results of those paths into a **Phase2** diagram.

7.1 Conceptual model

A **Phase2** calculation has three main components: the initial system, the staging reaction path, and the set of scanning reaction paths.

Phase2 begins a simulation by calculating the system's initial equilibrium state, which represents the bottom left corner of the diagram.

Beginning from that point, the program traces a staging path that defines the diagram's left margin. Along the staging path, **Phase2** changes the system, just as **React** does, by adding or removing reactants to vary the system's composition, changing the temperature, varying the fugacity of gases in an external buffer, and so on.

Starting from intermediate points along the staging path, the program initiates a series of scanning paths that trace a second reaction process. The two-dimensional grid of calculation results makes up the resulting **Phase2** diagram, which can be rendered using the **P2plot** program.

7.2 Staging and scanning paths

To configure the staging path, move to the **Y Axis** pane, where you can set reactants, activity and fugacity buffers, and fixed or varying temperature, much as you would on the **Reactants** pane in **React**

∲² Phase2	_	×
<u>E</u> ile <u>E</u> dit Run Config <u>V</u> iew <u>H</u> elp		
Basis X Axis Y Axis Medium Command Results		
reactants and polythermal reactions		
- React NaCl 100.0 T mmol T		
React NaCl 100.0 mmol cutoff temperature 25.0 C		
temperature 25.0 V C V		
add delete		
reactants times 1.0		
٢		>

In a similar fashion, you move to the **X** Axis pane to set reactants, buffers, and the temperature trajectory that define the scanning paths

ϕ^{z} Phase2							_		×
<u>F</u> ile <u>E</u> dit Ru	in Config <u>V</u> iew	/ <u>H</u> elp							
Basis	X Axis	Y Axis	Medium	Command	Results				
reactants,	kinetics, and polythe	ermal reactions							
- React	- React CaSO4 50.0 Tommol Tommol								
cutoff			▼ m	nmol					
	tem	perature		25.0	• c ·	•			
add d	lelete								
reactants tin	nes 1.0	•							
<									>

You may equivalently configure the staging and scanning paths from the **Command** pane. The commands

react y	100 mmol NaCl
react x	50 mol CaSO4

set the system's NaCl content to vary over the staging path, and its CaSO₄ composition to vary along the scanning paths.

The scope command lets you specify the target axis for subsequent commands. The commands above might be equivalently entered

```
scope y
react 100 mmol NaCl
scope x
react 50 mmol CaSO4
```

To set a polythermal axis, move to the **X Axis** or **Y Axis** pane, click the pulldown next to the unit for temperature, and choose "sliding temperature"

Upon selecting this option, two fields are available: "initial temperature" and "slide temperature to"

φ ² Phase2					_	×
<u>Eile E</u> dit Run Config <u>V</u> iew <u>H</u> elp						
Basis X Axis Y Axi	s Medium	Command	Results]		
reactants and polythermal reactions						
initial temperature		25.0	т с .	•		
slide temperature to		100.0	• c ·	•		
add delete						

In this case, the system begins at 25°C and warms to 100°C. The initial temperature represents the left-side temperature on the **X** Axis pane, or, on the **Y** Axis pane,

temperature at the diagram's lower left. Note that either axis, but not both, may be polythermal in a given run.

From the Command pane, use either the temperature command on a single line

temperature y initial = 25, final = 100

or within a scope block

```
scope y
temperature initial = 25, final = 100
```

You control the diagram's resolution by setting the "Nx" and "Ny" fields on the **Config** \rightarrow **Output...** dialog

plot dat XML	aset Nx 301 ▼ Ny 30 ● binary O character	1
title		
suffix]
	OK Apply Cancel	Reset

or using the "Nx" and "Ny" commands. Note that computing time and memory use increases as the product of the *x*- and *y*-direction resolutions, so you should avoid setting overly large values.

When you set a sliding buffer—a sliding pH, pe, Eh, activity, fugacity, or ratio—along one axis, **Phase2** automatically sets up the corresponding fixed buffer on the other. To make a "true" Eh-pH diagram, for example, you would set a sliding Eh path on the staging axis, and a sliding pH path on the scanning axis. In this case, the program fixes pH over the staging axis to the left-side value. Then, along each scanning path,

the program picks up Eh at the beginning of the path and holds it constant.

To see how this works, set a sliding Eh reactant on the **Y Axis** pane

φ²	Phase2									_	×
<u>F</u> ile	<u>E</u> dit	Run	Config	<u>V</u> iew	<u>H</u> elp						
	Basis		X Axis		Y Axis	Medium	Command	Results]		
	reactant	s and	polytherma	l reacti	ons						
	- Slide	Eh			to 1.0	• V	•				
				tempe	erature		25.0	▼ C 1	•		
	add	dele	te								

then move to the **X Axis** pane, where the setting "fix Eh" has been automatically applied

φ² Phase2						—	×
<u>F</u> ile <u>E</u> dit Run Config <u>V</u> i	iew <u>H</u> elp						
Basis X Axis	Y Axis	Medium	Command	Results]		
reactants, kinetics, and poly	thermal reactions				1		
Fix Eh							
t	emperature		25.0	▼ c	•		
add delete							

While on the **X Axis** pane, add a sliding pH path

ϕ^2 Phase2	_	×
<u>E</u> ile <u>E</u> dit Run Config <u>V</u> iew <u>H</u> elp		
Basis X Axis Y Axis Medium Command Results		
reactants, kinetics, and polythermal reactions		
Fix Eh		
- Slide pH to 9.0 ▼ pH		
temperature 25.0 V C V		
add delete		

Returning to the **Y Axis** pane, you will see the "fix pH" setting already applied

↓ ² Phase2	-	×
<u>E</u> ile <u>E</u> dit Run Config <u>V</u> iew <u>H</u> elp		
Basis X Axis Y Axis Medium Command Results		
reactants and polythermal reactions		
- Slide Eh to 1.0 V V		
Fix pH		
temperature 25.0 V C V		
add delete		

Time in **Phase2** can vary along only the scanning axis. You can, therefore, define kinetic reactions, use time rates to describe mass transfer, set internal heat sources, and so on, only along the *x* axis. You may also implement the special model configurations—flow-through, flush, and flash models—only along the horizontal.

Since time advances only along *x*, kinetic reactions are held at their initial states of disequilibrium everywhere along the staging axis. A mineral that reacts according to a kinetic rate law, for example, neither precipitates nor dissolves as the program traces the staging path. Then, as the program traces the scanning paths, the mineral reacts at the rate specified by its kinetic rate law.

7.3 Progress variables

Once **Phase2** has completed a calculation, it writes the results to a file "Phase2_plot.p2p", to be read by the plotting program **P2plot**. When you start **P2plot**, the plot axes will be labeled initially in terms of reaction progress. Start configuring your diagram by changing the axis variables to something more meaningful, and choosing whether to display the axes in linear or logarithmic coordinates.

Phase2 passes for each axis a list of potentially meaningful variables—the "progress variables"—to **P2plot**. The intent in choosing a progress variable along an axis is for its value to be invariant normal to the axis. In other words, scanning from one side of the diagram from a tick mark to the other, the progress variable should not change in value.

In many cases, such invariance is precise only if appropriate units are chosen. For example, if the *x* axis represents addition of Na⁺, choosing units of mol gives a diagram in which the axis reads correctly at any point along *y*. Setting units of mol/kg, on the other hand, might not map precisely if the salinity, and hence kg of fluid, vary along *y*. To verify validity of a progress variable, simply use **P2lot** to plot it against the counter-axis.

Each simple reactant is listed as a progress variable such as "Mass reacted, Al+++". If an original basis entry is added as a simple reactant and its total mass is not affected by other reactants, by charge rebalancing, or by special mass-transfer configurations, the component's total mass (e.g. "Al+++ in system") is also listed.

Consider the example

```
scope x
react 1 mol Na+
react 1 mol Cl-
scope y
react 1 mol K+
react 1 mol Cl-
```

On the x axis, "Mass reacted, Na+" and "Mass reacted, Cl-" are reported as progress variables, as is "Na+ in system". On the y axis, "Mass reacted, K+" and "Mass reacted, Cl-" are available, along with "K+ in system". No variable "Cl- in system" is available on either axis, though, because Cl^- concentration changes along both axes.

When an axis represents a sliding buffer, the buffered value and its logarithm are each available as a progress variable. If a time span is set for the scanning axis, time is also set as a progress variable. The "Mixing fraction" is listed as a progress variable along the scanning axis for flash models.

Temperature is available as a progress variable for a polythermal axis, for a simple sliding temperature run. For runs accounting for polythermal mixing or internal heat sources, in contrast, temperature is determined by the model, rather than prescribed, and so does not constitute a valid measure of progress along an axis.

7.4 Linear and log stepping

You should in general configure **Phase2** to step along an axis in a manner that matches how you envision rendering the final plot. If the axis is to be plotted on a linear scale, **Phase2** should step along the axis linearly, so that the plot points are evenly spaced along the axis. When an axis variable is to be rendered on a log scale, however, you should set up stepping along the variable's logarithm.

How you choose between linear and log stepping depends on the variable being rendered on the axis. Most progress variables, such as time, temperature, or mass reacted, step linearly by default, but can be set to vary logarithmically by setting the log argument to the delxi command.

When you set a sliding activity or fugacity reactant (see **Sliding activity and fugacity** in this guide) activity, fugacity, activity ratio, and fugacity ratio vary linearly, by default. To have **Phase2** step along the variable's logarithm, you constrain the reactant in terms of log units. The pH, Eh, and pe always vary linearly in sliding paths.

In a simulation spanning 100 days, for example, a run with linear stepping might report evenly-spaced results at 0, 50, 100, and so on, days. A run with log stepping, however, might give output at 1, 10, 100, and so on, days. The initial condition, corresponding to 0 days in this example, is not displayed in plots with logarithmic axes.

Consider a case in which you want to display the concentration of a component on a logarithmic scale. The commands

```
scope y
react 1 mol Na+
delxi .01 log
```

will add 0.01 moles of Na⁺ in the first step (corresponding to Xi = .01), then continue taking log steps until the entire 1 mole has been added. A plot of Na⁺ reacted might show the variable with evenly spaced ticks at 0.01, 0.1, and 1 mole.

You can combine the $\tt delxi$ and $\tt dx_init$ commands to give detail at the beginning of a path. The commands

```
scope y
react 1 mol Na+
delxi .01 log
dx init = 1e-5
```

will cause the program to add 10^{-5} moles in the first step (corresponding to Xi = 1e-5), and then proceed with log steps until the entire mole has been added. In this way, a plot of Na+ reacted might show the variable with evenly spaced ticks at 10^{-5} , 10^{-4} , 0.001, 0.01, 0.1, and 1 mol.

You may commonly find need for plotting the "total concentration" of a species (e.g. Na⁺ in system) as a progress variable, rather than the amount reacted. In this case, the initial concentration (e.g., Na⁺) specified in the **Basis** pane should be negligibly small, but nonzero. A value roughly 4 orders of magnitude smaller than the value corresponding to the first step works well. A constraint of 10^{-6} mol/kg Na⁺ would work well for the first example described above, but 10^{-9} mol/kg might be used for the second example.

7.5 Settable variables

Phase2 allows you to alter the values of certain variables carried in the calculation. **Table 7.1** lists variables that differ from those carried by **React** (see **Table 2.1**), along with their units and default values.

Table 7.1	Settable variables ir default values	Settable variables in Phase2 differing from React, their units and default values									
Pane or Dialog	Variable	Default	Unit	Description							
Stepping	delxi x y	.01	-	Step size in reaction progress, log/linear stepping.							
	dx_init x y	not set	-	Initial step size in reaction progress.							
	step_increase x y	1.5	-	Maximum proportional increase in step size.							
	step_max x y	not set	-	Number of reaction steps the program may take in any single path.							
	threads	equal to number of cores	-	Number of threads to spawn, for parallel execution.							
Output	dxprint x y	.1	-	Interval between printing results.							
	Nx, Ny	301, 301	-	Number of data points in the plot grid							

Table 7 1 Settable variables in Phase2 differing from Peact their units

To change a variable, type the new value on the **Basis** or **Medium** pane or in the dialog boxes under **Config**, or enter as a command the variable name followed by the new value. Examples:

Nx = 101delxi y = 0.1 log dx init y = 1e-10

Variables accepting an x or y argument can alternatively be set within a scope block:

```
scope y
   delxi = 0.1 \log
   dx init = 1e-10
```

Values are entered in the units carried internally by the program, as listed in **Table 2.1** or **Table 7.1**. To restore a variable to its default value, enter a blank field in the dialog box, or on the **Command** pane type its name without a value or followed by a "?":

Nx Nx = ?

Current settings can be viewed at any time on the relevant dialog box, or using the command show variables.

7.6 Multicore execution

Phase2 is multithreaded in such a way that multicore computers trace the scanning paths in parallel. Like **X1t** and **X2t**, described in the *GWB Reactive Transport Modeling Guide*, you can control the number of threads **Phase2** spawns on the **Config → Stepping...** dialog, or with the threads command.

From the same dialog, or with the pluses command, you can control the amount of output shown on the **Results** pane after each step. Like **X1t** and **X2t**, **Phase2** reports upon completion of a calculation the computing time needed to execute parallel and serial sections of the code, as well as the clock time elapsed over the run.

7.7 Running a model

Once you have configured a simulation, you are ready to run it. A number of example input files for **Phase2** are installed with the GWB Professional package, in subdirectory "Script" within the installation directory (e.g., in "\Program Files\GWB\Script"). The example files have ".ph2" extensions. To give the program a test drive, double-click on one of the files.

Start the simulation in any of several ways: selecting **Run** \rightarrow **Go**, pressing **Ctrl+G**, typing go on the **Command** pane, or clicking the **Run** button on the **Results** pane. You can watch on the **Results** pane as the model follows the simulation procedure, first computing the initial conditions, then tracing the staging reaction path, and finally tracing each scanning reaction path.

When the calculation is complete, click on the **Plot Results** button to launch **P2plot**. This program lets you render the simulation results graphically, as two-dimensional diagrams, in which you render the results as maps of species predominance or mineral assemblages. You can also color map and contour any variable. Additionally, you can plot cross-sections through the diagram. The chapter **Using P2plot** in this guide gives further details.

You can have the model produce text-format or "print" results describing the chemical state, along with the isotopic state, if applicable, at each stage of the calculation. To do so,

select **Config** \rightarrow **Output...** and then select the "print dataset" option. The program will write results at intervals in the reaction progress (ξ) set by variable "dxprint" on the **Config** \rightarrow **Output...** dialog. When the model is complete, click on **View Results**. The print option can produce large amounts of output and, therefore, is by default turned off.

After finishing a simulation, you can revise the model configuration and run it again. When the new simulation is complete, any instances of **P2plot** running on your computer will automatically update their plots to reflect the latest results. You can open several **P2plot** windows on your computer at the same time, allowing you to view results plotted in different ways.

By clicking on $\mathbf{Run} \rightarrow \mathbf{Go}$ Initial or typing go initial, you cause the program to evaluate the initial conditions without tracing either the staging or scanning reaction paths. You can also click on $\mathbf{Run} \rightarrow \mathbf{Go} \mathbf{Y}$ or type go y to trace the staging path (the left edge of the diagram). Similarly, click on $\mathbf{Run} \rightarrow \mathbf{Go} \mathbf{X}$ or type go x to trace a single scanning path (the bottom edge of the domain). Once done, you can render the initial conditions with **P2plot**, as you could the results of any simulation. These features are handy because they let you verify that the initial system or either reaction path is set up correctly, without completing the entire simulation.

7.8 Example: Speciation diagram

As a first example, we construct a "true" fO_2 -pH diagram for the copper-sulfur-water system at 250°C. Double-click on file "CuSH2O.ph2" to launch **Phase2** and move to the **Basis** pane

Basis	X Axis	Y Axis	Medium	Command	Results				
Constraints on lower left corner of diagram									
		H2O		1.0	▼ free kg ▼	solvent			
		Na+ 🛱		50.0	▼ mmol/kg ▼	charge balance			
		d- ₽		50.0	▼ mmol/kg ▼				
		HS- ₽	SO4	1.0	▼ mmol/kg ▼				
		Cu+ 🛱		10.0	▼ umol/kg ▼				
		02(g) 🛱	O2(aq)	-50.0	▼ log fugacity ▼				
		н+ 🛱		3.0	▼ pH ▼				
	temp	erature		250.0	▼ C ▼				
				+ advanced					
add	delete								

Here we constrain the chemical system at the bottom-left corner of the diagram: the background electrolyte is 50 mmol/kg NaCl, and the fluid contains 1 mmol/kg sulfur and 10 μ mol/kg copper. The corner marks a log fugacity of –50 and a pH of 3.

The **Y Axis** pane sets up the staging axis

	H2O.ph2						_	×
<u>F</u> ile <u>E</u> dit Run	Config <u>V</u> iew	v <u>H</u> elp						
Basis	X Axis	Y Axis	Medium	Command	Results]		
_ reactants and	polythermal reac	tions						
+ Slide log fu	gacity of O2(g) t	o 5						
Fix pH								
	temp	perature		250.0	• c ·	•		
add dele	te							
reactants times	1.0	•						
<								>

such that the logarithm of oxygen fugacity slides to 5, while pH holds constant. In contrast, the **X Axis** pane

φ ² Phase2 : Cu	SH2O.ph2						_	×
<u>F</u> ile <u>E</u> dit Ru	n Config <u>V</u> ie	w <u>H</u> elp						
Basis	X Axis	Y Axis	Medium	Command	Results]		
reactants, k	inetics, and polyt	nermal reactions						
Fix fuga	city of O2(g)							
+ Slide pH	to 11							
	ter	mperature		250.0	• C	•		
add d	elete							
reactants tim	1.0	•						
<								>

fixes fugacity, but slides pH to 11.

You can alternatively use the commands

```
T = 250 C
             = 50 \text{ mmol/kg}
Na+
Cl-
             = 50 \text{ mmol/kg}
balance on Na+
swap HS- for SO4--
HS-
        = 1 \text{ mmol/kg}
Cu+
           = 10 umol/kg
swap O2(g) for O2(aq)
O2(g) = -50 \log fugacity
рΗ
             = 3
scope y
   slide log fugacity of O2(g) to 5
scope x
   slide pH to 11
```

from the **Command** pane to configure the same calculation.

Move to the **Results** pane and click **run** to trigger the calculation. When the program finishes, choose **Plot Results** to open dataset "Phase2_plot.p2p", which holds the calculation results, in program **P2plot**.

In **P2plot**, select **Plot** \rightarrow **2D Diagram**. When the diagram displays, double-click on one of the axis variables (or go to **Format** \rightarrow **Axis Range and Variables...**) and on the **X Axis** tab set "Progress Variable" to "pH"

Axis Y Axis			
Progress variable	рH		~
Auto-scale	Reverse axis		
Minimum	3	*	
Maximum	11	-	
Tick increment	1	🗘 linear	~

Then, on the **Y** Axis tab, set the variable for the *y* axis to "log f O2(g)".

Next, click on **Format** \rightarrow **Predominance Map...** to expose the Predominance Map dialog. Check the box next to "Predominance Map", if it is not already, and next to "Variable to map" choose "Cu+"

Predominance Map		×
Predominance Map		
Variable type	Basis species	~
Variable to map	Cu+	\sim
Aqueous fields	All aqueous species	~
Surface fields	All surface species	~
Mineral fields	All minerals	~
🗹 Gas fields	All gases	~
Don't color fields		
Bounds	1 pt — 🗸 📕	Smooth lines
☑ Water limits	14pt — 🗸 📕	🗹 Truncate
🗹 Labels	22 pt ≑ 📕	BI
ок	Apply Cano	el Reset

Click on Apply.

The resulting diagram shows the predominant copper-bearing species and minerals at 250°C as a function of pH and oxidation state

The plot is truncated at low and high fO_2 by the upper and lower stability limits of water. To extend the diagram, return to the **Predominance Map** dialog, uncheck "Truncate", and click on **Apply**. To diagram predominant sulfur-bearing species, return to the dialog, change the "Variable to Map" to "SO4--", and once again hit **Apply**.

7.9 Example: Mineral solubility

The input file "AlSolubility.ph2" calculates the solubility of aluminum in the presence of quartz as a function of pH and the system's aluminum content. Double-click the file to launch **Phase2**. The **Basis** pane

d ³ Phase2 : AlSolubility.ph2	_		\times
<u>E</u> ile <u>E</u> dit Run Config <u>V</u> iew <u>H</u> elp

<							>

pH is set to slide from 3, the starting point, to a final value of 8.

On the **Config → Stepping...** dialog

ϕ^{z} Stepping						×
delQ		0.1	•	theta	0.6	7-)
dx_init	x		•	у	0.0001	•
delxi	x	0.01	•	у	0.01	•
step_increase	x	1.5	•	У	1.5	
stepping	x	 linear 		У	Olinear	
		◯log			● log	
explain step	os		pr	rogress	off	•
			th	nreads	8	_

we set logarithmic stepping along the *y* axis, with an initial step size of 10^{-4} . Since we're ultimately adding 10^{-5} moles of Al⁺⁺⁺, **Phase2** will add $10^{-4} \times 10^{-5} = 10^{-9}$ moles to the initially negligible mass on the first step, then exponentially larger aliquots as it takes subsequent steps.

Press the **Run** button on the **Results** pane to trace the calculation. Start **P2plot** by clicking on the **PotResults** button and select **Plot** \rightarrow **2D Diagram**. Double-click on the *x* axis label and set "Progress Variable" to "pH". Move to the **Y axis** tab and set "Progress Variable" here to "Al+++ in system" with a log scale. Adjust the tick increment on each axis, if you wish, by de-selecting "Auto-scale", and click **OK**.

Next, select **Format** → **Assemblage Map...**, check the box at the top of the dialog, and click **OK**. Select **Format** → **Contour Map...** and check the box at the top of the dialog. Next to "Variable type", choose "Components in fluid", set "Variable to contour" to "Al+++", and for "Variable units", set "umol/kg". Make sure "Type of plot" is "Log", adjust the point size and color of the contour lines to your liking, and click OK.

The resulting diagram

delineates the stability of kaolinite in the presence of quartz, and contours the logarithm of aluminum solubility, in μ mol/kg.

7.10 Example: Gas solubility

In this example we diagram the solubility in water of atmospheric $O_2(g)$ as a function of salinity and temperature. Our strategy is to define a dilute fluid in equilibrium with the atmosphere at 0°C to occupy the lower-left corner of the diagram. We will then set temperature to increase along the staging axis, and salinity along the scanning axis, while holding $O_2(g)$ fugacity constant across both axes.

Begin by double-clicking on file"O2Solubility.ph2" to launch Phase2. The Basis pane

d ² Phase2 : O2Solubility.ph2 ≤	– 🗆 X
<u>F</u> ile <u>E</u> dit Run Config <u>V</u> iew <u>H</u> elp	
Basis X Axis Y Axis Medium Command	Results

	slide tempe	erature to		100.0	• c •		
add d	elete						
reactants tin	nes 1.0	-					
<							>

slides temperature along the staging path, and the X Axis pane

↓ ² Phase2 : O	2Solubility.ph2						_	×
<u>F</u> ile <u>E</u> dit Ru	ın Config <u>V</u> ie	w <u>H</u> elp						
Basis	X Axis	Y Axis	Medium	Command	Results			
-reactants, l	kinetics, and polyth	nermal reactions						
+ React 3	mol of Na+							
+ React 3	mol of Cl-							
Fix fuga	city of O2(g)							
	ten	nperature		0.0	• c •	•		
add d	lelete							
reactants tim	nes 1.0	•						
<								>

sets up a titration of 3 mol of Na⁺ and Cl⁻ as simple reactants along the scanning paths.

The simulation, then, consists of a series of isothermal titration paths, each traced at fixed oxygen fugacity, and each maintaining the temperature of its point of departure from the staging path. Press the **Run** button on the **Results** pane to trace the calculation.

Press **PlotResults** to launch **P2plot**, then select **Plot** \Rightarrow **2D Diagram**. Double-click on one of the axis variables (or go to **Format** \Rightarrow **Axis Range and Variables...**), then set the *x* axis progress variable to "Cl- in system", with units of "mmol/kg", and the *y* axis variable to "Temperature". Now, select **Format** \Rightarrow **Contour...** to expose the contour plot dialog. Choose "Species concentrations", "O2(aq)", "mmol/kg", and "Linear" in the top four fields, then check the box next to "Contour Lines" and click on **Apply**. Under **Format** \Rightarrow **Color Map...**, choose the same settings and hit **Apply**.

The resulting diagram shows how oxygen solubility decreases with increased temperature and salinity

The diagram reflects how the log K of the reaction between $O_2(g)$ and $O_2(aq)$ decreases with temperature, while the activity coefficient of $O_2(aq)$ increases with ionic strength. The latter effect is commonly known as the "salting out" effect.

7.11 Example: Isotope fractionation

In this example, we diagram the ¹³C composition of $CO_2(g)$ in equilibrium with a carbonatebearing fluid of known carbon isotopic composition, as a function of pH and temperature. Double-click on file "CO2_frac.ph2" and when **Phase2** opens, move to the **Basis** pane

φ ² Phase2 : CO2_frac.ph2			_

		ОК	Apply	Cancel	Reset	:

we set δ^{13} C of the fluid to -20 _{∞} PDB. There is in the simulation no external source or sink of 13 C, and no mineral precipitates, so the fluid's bulk isotopic composition remains constant across the diagram.

Press the <u>Run</u> button on the **Results** pane to trace the calculation. Start **P2plot** by clicking on the <u>PlotResults</u> button. In **P2plot**, select **Plot** \rightarrow **2D Diagram**, then click on **Format** \rightarrow **Axis Range and Variables...** to set the axis variables to "pH" along the *x* and "Temperature" along the *y* axis.

Next, click on **Format** \rightarrow **Color Map...** and check the box on the top line. Next to "Variable type", choose "Isotopic composition", for "Isotope system" choose "13-C", and then set "Variable to map" to "CO2(g)". Adjust the colors as you like and click **OK**. Now, open the **Format** \rightarrow **Contour...** dialog, make the same settings for "Variable type", "Isotope system", and "Variable to map", then set the appearance options to your liking,

and again click **OK**. Finally, click **Format** → **Predominance Map...** and check the box on the top line. Choose "HCO3-" for "Variable to map", then check "Don't color fields" and hit **OK**. The latter option displays predominance bounds and labels without coloring the fields, thus allowing the color map we've applied to remain visible.

P2plot at this point should display a diagram similar to

As we see, the isotopic composition of $CO_2(g)$ in equilibrium with the fluid varies with pH in response to the changing balance between $CO_2(aq)$ and the carbonate species HCO_3^- and CO_3^- , and along the vertical axis as the isotopic fractionation factors shift with temperature.

7.12 Example: Surface complexation

Input file "ZnSorption.ph2" sets up calculation of a diagram showing the controls of pH and Zn^{++} content on the metal ion's surface complexation with ferric hydroxide. Double-click the file to launch **Phase2** and move to the **Basis** pane

Basis	X Axis	Y Axis	Medium	Command	Results

Zn⁺⁺ is titrated into the system while pH is held constant. The **X Axis** pane

φ ² Phase2 : ZnSorption.ph2	_	×
<u>F</u> ile <u>E</u> dit Run Config <u>V</u> iew <u>H</u> elp		
Basis X Axis Y Axis Medium Command Results		
reactants, kinetics, and polythermal reactions		
+ Slide pH to 12		
temperature 25.0 V C V		
add delete		
reactants times 1.0		
<		>

slides pH from its initial value of 4 at the left of the diagram, to 12 at the right. On the **Config → Sorbing Surfaces...** dialog

ϕ^2 Sorbing Surfaces			_	
HFO (two layer) C:\Program Files\Gwb\Gtdata\FeOH.sdat constant capacitance				
mobility + 0.0 -				
add delete				
	ОК	Apply	Cancel	Reset

we see that the Dzombak and Morel dataset for ion complexation with hydrous ferric oxide is loaded.

On the **Config → Options...** dialog

Options	
_ options	
Kd precipitation sorbate	
gas pressure model default	
_ density	
method Batzle-Wang	
use NaCl fluid of same TDS Chlorinity	
⊂log K span	
span min ▼ C ▼ max	• c •
OK Apply Cancel	Reset

the "precipitation" option has been unchecked, preventing new minerals from forming during the simulation. Finally, the "sorbate" option here has been checked, specifying that the concentration of Zn^{++} set on the **Basis** pane represents the sum of the basis entry's dissolved and sorbed masses.

Press the **Run** button on the **Results** pane to trace the calculation, then start **P2plot** by clicking on the **PotResults** button. In **P2plot**, select **Plot** \rightarrow **2D Diagram**. Then, on the **Format** \rightarrow **Axis Range and Variables...** dialog, set "pH" on the *x* and "Zn+++ in system" on the *y* axis, and click **OK**. Select **Format** \rightarrow **Predominance Map...** and choose "Zn++" for "Variable to map", then hit **Apply**. Go to **Edit** \rightarrow **Contour...**, check the box at the top, and choose "Sorbed fractions" for "Variable type", and "Zn++" for "Variable to contour". Make sure to select a "Linear" mapping, set the appearance and contour interval to your liking, and hit **Apply**.

As is typical of a divalent metal, Zn⁺⁺ does not sorb at low pH. Under neutral to alkaline conditions, the strong sites account for most of the sorbed Zn⁺⁺ where the system contains little Zn⁺⁺. At higher zinc contents, however, the weak sites hold most of the zinc in the system, due to their greater abundance relative to the strong sites. Along the top of the diagram, the capacity of the ferric hydroxide to hold zinc is overwhelmed, and most of the metal is found in solution.

7.13 Example: Kinetic diagram

The input file "Promoting.ph2" builds on a **React** calculation borrowed from the section **Kinetics of redox reactions** in the **Kinetic Reaction Paths** chapter of this manual. In that example, contained in dataset "Redox.rea", ferrous iron oxidizes to ferric hydroxide according to a kinetic rate law. In the rate law, OH⁻ promotes the oxidation reaction with a power of 2.

In this section, we construct a **Phase2** diagram showing how pH, which controls OH⁻ concentration, affects the oxidation rate. Opening "Promoting.ph2", the **Basis** pane

φ ² Phase2 : Promoting.ph2			- 🗆 ×
<u>F</u> ile <u>E</u> dit Run Config <u>V</u> iew <u>H</u> elp			
Basis X Axis Y Axis	Medium	Command Results	
constraints on lower left corner of diagram			
H2O		1.0 Tree kg 🔻	solvent
Fe(OH)3(ppd) 🛱	Fe+++	1.0 The ug T	
н+ 🛱		6.7 v pH v	
02(g) 🛱	O2(aq)	0.2 Tugacity T	
Na+ 🛱		1.0 mmolal T	
a- ₽		1.0 mmolal T	charge balance
Fe++ ₽		30.0 The mmolal The mm	
temperature		10.0 • C •	
		+ advanced	
add delete			
⊡ time start 0.0 ▼ day ▼	end 20.0	▼ day ▼	
<			

is much like that in the **React** example, except the pH is set slightly lower, to 6.7.

The Y Axis pane

φ ² Phase2 : Pr	omoting.ph2					_		×
<u>F</u> ile <u>E</u> dit Ru	in Config <u>V</u> ie	ew <u>H</u> elp						
Basis	X Axis	Y Axis	Medium	Command	Results			
- reactants ar	nd polythermal rea	actions						
+ Slide pH	to 7.3							
Fix fuga	Fix fugacity of O2(g)							
	ter	mperature		10.0	▼ C ▼			
add d	elete							
reactants tim	les 1.0	•						
<								>

sets up a staging path along which pH varies from its initial value at the bottom of the diagram to 7.3 at the top. The fluid is to remain in equilibrium with the atmosphere, so oxygen fugacity needs to be buffered here, as well as on the **X** Axis pane.

The settings on the **X Axis** pane

↓ ² Phase2 : Pr	omoting.ph2						_		×
<u>F</u> ile <u>E</u> dit Ru	in Config <u>V</u> iev	w <u>H</u> elp							
Basis	X Axis	Y Axis	Medium	Command	Results				
reactants, k	reactants, kinetics, and polythermal reactions								
Fix pH									
+ Kinetic r	+ Kinetic redox-1 = Fe++ + .25 O2(aq) + 2.5 H2O -> Fe(OH)3(ppd) + 2 H+								
Fix fuga	Fix fugacity of O2(g)								
	tem	perature		10.0	• c •	•			
add delete									
reactants tim	1.0	•							
<									>

fix pH according to the departure point on the staging path, define the kinetic rate law, and hold oxygen fugacity constant. The rate law entry, once expanded, is unchanged from the **React** example; notably, OH⁻ serves as a promoting species.

Press the **Run** button on the **Results** pane to trace the calculation, then start **P2plot** by clicking on the **PotResults** button. Select **Plot** \rightarrow **2D Diagram**, set the *x* axis variable to "Time" in days, and the *y* axis to "pH".

Predominance Map		×
🗹 Predominance Map		
Variable type	Element	~
Variable to map	Iron	\sim
Aqueous fields	All aqueous species	~
Surface fields	All surface species	~
Mineral fields	All minerals	~
Gas fields	All gases	~
Don't color fields		
Bounds	1 pt — 🗸 📕	Smooth lines
	¼pt— ↓ 📕	🗹 Truncate
Labels	22 pt 🖨 📕	BI
ОК	Apply Cano	el Reset

Open the **Format** → **Predominance Map...** dialog. Change the "Variable type" pulldown from "Basis species" to "Element", select "Iron" as the "Variable to map"

and hit **Apply**. Set in this way, the predominance diagram will include both ferrous and ferric iron-bearing species and mineral.

Open the **Format** \rightarrow **Contour...** dialog and check the box at the top. Choose "Reactant properties" for "Variable type", and for "Variable to contour, select "Reaction rate, redox-1 (x)". Set "Variable units" to "mmol/kg/day" and, for "Type of plot", set "Log". Choose appearance options and a contour increment to your liking, and press **Apply**.

As reflected by the contours of log reaction rate, reaction proceeds faster as pH increases, reflecting the role of the hydroxyl ion as a promoting species in the kinetic rate law. Along x, the reaction slows with time as another promoting species, the Fe⁺⁺ ion, is depleted over time.

7.14 Cross-section plots

P2plot can diagram cross-sections through any diagram. You makes *x*-*y* plots of a broad range of variables such as pH, species concentration, mineral mass, gas pressure, isotopic composition, and so on.

To plot along a cross-section, select **Plot** \rightarrow **Cross-section Plot...** to expose the configuration dialog. On the **X Axis** pane, choose the section's orientation by setting "Orientation" to either "Along scanning paths" or "Across scanning paths". On the **Y Axis** pane, if the orientation is along the scans, set "Display" to "Several values at one step along y" or "One value at several steps along y". Plotting across the scans, the choices both read "... along x".

Now, on the **X Axis** pane, select a category from the "Variable type" dropdown and choose the *x*-axis variable from the list. Similarly, set "Variable type" on the **Y Axis** pane. At this point, depending on the "Display" setting, you can choose either several variables on this pane and a single step on the **Step** axis, or one *y*-axis variable and several steps.

As an example, re-run file "ZnSorption.ph2", launch **P2plot**, and select **Plot** \rightarrow **Cross-section Plot...** On the **X Axis** pane, set "Orientation" to "Along scanning paths" and choose to plot "pH" among the "Chemical parameters"; under **Y Axis**, set "Variable type" to "Species concentration", "Filter" to "Zn++", "Display" to "Several values at one step along y", and then set a "linear" scale. Click on **Select all**, if necessary. Moving to the **Step** pane, set "Progress variable" to "Zn++ in system", set the unit to "mmol", and choose "Zn++ in system = .1 mmol".

The resulting plot should look like

Here, the Zn⁺⁺ ion is present in free form under acidic conditions, but complexed with strong and weak sites on the ferric surface at neutral to alkaline pH.

We can alternatively plot one variable at several points along the staging axis. Return to the **Y Axis** pane, set "Display" to "One value at several steps along y" and then "Variable type" to "Sorbed fractions". On the **Step** pane, choose "Zn++ in system = 1 mmol", hold down the Ctrl key while selecting the corresponding entries for "... 2 mmol" and "... 3 mmol", and click **Apply**.

The resulting plot should look like

As more Zn⁺⁺ is added to the system, a lesser fraction of it sorbs to the ferric hydroxide.

As a final example, we make a vertical section through the diagram. Returning to the **X Axis** pane, change "Variable type" to "Components in fluid", set "Orientation" to "Across scanning paths", and choose "Zn++" from the list. On the **Y Axis** pane, set "Variable type" to "Components in sorbate" and again choose "Zn++" from the list.

On the **Step** pane, set "Progress variable" to "pH" and choose the pH values closest to 5, 6, 7 and 8, then click on **Apply**. The resulting plot

Using Phase2 187

shows the $Zn^{\scriptscriptstyle +\!+}$ sorption isotherms at the pH values of interest.

7.15 Phase2 command line

You can start **Phase2** by clicking the icon on the GWB dashboard, opening a ".ph2" file, or entering the command phase2.exe from the Windows "Command Prompt". When you start **Phase2** from the command line (as opposed to clicking on the icon), you can specify a number of arguments. For example, the command

```
phase2 -i my_script -d my_thermo.tdat
```

causes **Phase2** to read input commands from a file "my_script", and to use "my_thermo.tdat" as the thermodynamic database.

-cd	Change the working directory to the directory containing the input script specified with the –i option.
-nocd	Do not change the working directory.
-i <input_script></input_script>	Set a file from which to read input commands.
-gtd <gtdata_dir></gtdata_dir>	Set directory to search for thermodynamic datasets.
-cond <cond_data></cond_data>	Set the dataset for calculating electrical conductivity.
-d <thermo_data></thermo_data>	Set the thermodynamic dataset.
-iso <isotope_data></isotope_data>	Set the dataset of isotope fractionation factors.
-s <surface_data></surface_data>	Set a dataset of surface sorption reactions.

The following options are available from the command line:

Using P2plot

P2plot is a graphics program that produces various types of diagrams showing the results of **Phase2** calculations. The program is similar to **Gtplot** and **Xtplot**, so if you have familiarized yourself with these programs, you already know much of what you need to know to run **P2plot**.

After running **Phase2**, start **P2plot** by clicking on **Plot Results** on the **Results** pane, or selecting **Run > P2plot** from **Phase2**'s menubar. The program will read the calculation results from the ".p2p" file **Phase2** produced and render them graphically. You can leave **P2plot** active when you run further **Phase2** simulations. Each time **Phase2** completes a run, it signals **P2plot**, which updates its display to reflect the new results.

You can also start **P2plot** by opening any ".p2p" or ".p2c" file, or by clicking on the **P2plot** icon on the Apps pane of the GWB dashboard. You can take input from a different dataset by dragging the dataset into the **P2plot** window, or choosing **File** \rightarrow **Open** \rightarrow **Data File...** from the menubar. Depending on the plot you choose, **P2plot** might look like

P2plot produces plots of various types. You can generate a two-dimensional rendering of the results, showing the predominant form of any original basis species or element, or a map of mineral assemblages. You can also show one or several variables represented by color shading or contours.

Alternatively, you can plot cross-sections through the diagram that show how certain variables change with reaction progress along staging or scanning paths. You can plot one or more variables from a single section, or one variable from several cross-sections.

Choose the diagram type from the **Plot** pulldown on the menubar. The program can render the following types of variables:

- Mass and volume of minerals and end members in the modeled system
- Concentration, activity, and activity coefficients of dissolved species
- Elemental composition of the fluid, minerals, sorbate, and the bulk system
- Composition of the fluid, minerals, sorbate, and the bulk system, expressed in terms of thermodynamic components
- Gas fugacity and partial pressure
- Saturation indices Q/K with respect to various minerals and solid solutions
- Bulk stable isotopic composition of the fluid, rock, sorbate, and the entire system, as well as the composition of individual species, gases, minerals, and end members
- Fraction of various components sorbed onto mineral surfaces
- Variables such as temperature, pH, and reacted mass

When **P2plot** starts for the first time in a given directory, it assumes a default configuration. Upon finishing, the program saves for its next run a dataset containing the current configuration of the plots. You can select options from the **File** menu to specify an alternative configuration (see **Loading and saving plot configuration**) or to reset the entire program configuration.

8.1 2D Diagram

P2plot makes two-dimensional diagrams, in which variables are represented by color shading, color masking, and contour lines. You can plot species' fields of predominance, or mineral assemblages. For two-dimensional plots, the **Format** menu contains a number of configuration options

- **Quick Toggle...** to select the graphical elements of the plot to display
- Color Map... to define a shaded color map of a variable over the diagram axes
- **Color Mask...** to color mask of a variable's value range over the diagram axes
- **Contour...** to choose a variable to contour and configure the contouring
- Predominance Map... to plot the species accounting for the most mass of any original basis species or element

- Assemblage Map... to plot fields representing every mineral or combination of minerals over the diagram axes
- **Appearance...** to open a tabbed dialog containing the following:
 - **Axes and Ticks...** to define the appearance of the coordinate axes
 - Plot Area... to choose the dimensions, placement, and background color of the plot
 - **Title...** to define a title for the plot
 - **Font...** to control aspects of the text throughout the diagram
- Axis Range and Variables... to select the two variables appearing on the diagram's axes and adjust the range and tick increment
- Side Banner... to specify the appearance and placement of the informational banner along the side of the plot
- Trace... to overlay the trace of a reaction path calculated with React
- GSS Data... to affect the labeling of scatter data loaded from a GSS spreadsheet and the related legend

Alternatively, you can interactively modify many aspects of the plot, including lines, labels, axes, scales, and grid lines. A **right-click** on an aspect displays a menu showing the options available. A **double-click** on an aspect brings up a related dialog. **Left-click** on an aspect to select it for modification.

An aspect has been selected when its color changes, as in the case of lines, or when it is surrounded by manipulation handles, in the case of text, markers, and scales. Change the size of text, markers, scales, and the plot itself by dragging the sizing cursors. Adjust the placement of the plot by clicking within the plot or on either axis and dragging it. The plot title can be moved in the same way.

8.1.1 Predominance Maps

A predominance map shows the aqueous species, surface species, mineral, or end member that accounts for the greatest mass of any component or element. A gas predominates if its partial pressure exceeds the system pressure, which corresponds to the temperature.

Use the **Predominance Map...** dialog to control aspects of the map. First select the species you'd like to diagram. Sort by thermodynamic components by selecting "Basis species"

Predominance Map		×
Predominance Map		
Variable type	Basis species 🗸 🗸	
Variable to map	Se03 ~	

or by elements by selecting "Element"

Predominance Map		×
Predominance Map		
Variable type	Element	/
Variable to map	Selenium	/

In many cases the resulting diagrams will be identical, but the latter option is especially useful for plotting decoupled redox species together.

You can hover on the plot to see the number of moles of the selected basis entry or element in the predominant species. For a gas, the partial pressure is reported.

By default all types of species are considered in the diagram, but you can hide any class by unchecking the appropriate box. In the example below

aqueous species, surface species, and minerals predominate at some point. Uncheck "Mineral Fields"

to ignore them in the tabulation of most abundant species.

Note, **P2plot** does not account for the combined mass of basis species or elements from each end member in a solid solution phase when figuring predominance. In a calcite-rhodochrosite solid solution, for example, the phase contains bicarbonate from both end members, but each end member is treated separately in determining species predominance.

Predominance maps by default draw lines representing the stability region of water and do not display species outside this region. Water is treated as unstable anywhere the partial pressure of $O_2(g)$ or $H_2(g)$ exceeds the confining pressure corresponding to the temperature of the calculation. Uncheck "Water Limits"

to ignore the stability limits. Or, with "Water Limits" checked, uncheck "Truncate" to draw outside the stability limits.

The Tables section of the thermo dataset shows the temperature expansion for pressure, either as a *T*-table or polynomial coefficients. The **Thermo Datasets** chapter in the *GWB Reference Manual* describes thermo datasets and the *GWB Essentials Guide* includes a description of the **TEdit** app used to view and modify the datsets.

Each type of field (Aqueous, Surface, Mineral, Gas) is colored differently by default. All minerals and end members, for example, are colored a light orange ("Old lace"). Click on the colored square next to a species type (e.g. All minerals) to change the color for that field. To set the color of an individual species, select it from the pulldown, then pick a color. To change the color of elemental selenium, for example, change the pulldown next to "Mineral Fields" from "All minerals" to "Se(black)", then click on the color box to pick a color.

	0	-	I	1 1	-	ace)		
				SeO4	Predominance Map		:	×
	–15			7	Predominance Map			
			>(w)FeS		Variable type	Basis species	\sim	
g)	-30	H ₂ SeO ₃ H	SeO ⁻ ₂ >(w)	FeOHSeO	Variable to map	Se03	\sim	
$0_{2}^{0}($					Aqueous fields	All aqueous species	\sim	
log f O ₂ (g)	-45	-			Surface fields	All surface species	~	
<u> </u>	-60	_	Se(black	()	Mineral fields <	Se(black)	~	>
	-00			F	Gas fields	All gases	~	
	-75				Don't color fields			
		ℍℷ⅁ⅇ		HSe	Bounds	1 pt — 🗸 📕	Smooth lines	
	-90 2	2	4	6 8		14pt — 🗸 📕	🗹 Truncate	
				pН	🗹 Labels	22 pt 🔹 📕	B	
					ОК	Apply Cano	el Reset	

The FeSe₂ keeps its original color, but the Se(black) field has been updated.

You can select "Don't color fields" to draw predominance bounds and labels without coloring the fields. In this way, you can overlay the bounds on another map type, such as a color map or assemblage map.

You can additionally change the color and thickness of lines separating species, as well as the water stability limits, and the size, color, and style of labels.

8.1.2 Assemblage Maps

Assemblage maps show fields in which a mineral or group of minerals exist in the calculation. You can hover over any field to see the assemblage of minerals present. Where no minerals form, the hover text displays "No minerals". Note, a pair of solid solution end members represents a single phase.

Use the **Format** \rightarrow **Assemblage Map...** dialog to control aspects of the diagram. All assemblages plot in the same color by default, but you can color assemblages individually, in the same way described above for predominance fields.

Depending on the number of unique mineral assemblages present in a calculation, and the number of minerals defining each assemblage, assemblage maps can become quite crowded. Use the "Label type" pulldown to control whether full names, shortened names, or a number representing each assemblage labels each field. You can remove the labels entirely by unchecking the "Labels" box. A legend, which you can toggle on or off with the "Legend" box, lists each assemblage present and displays the field color, abbreviations, and/or index for each assemblage. In the example below

	Assemblage Map		×
	Assemblage Map		
	Assemblage color	All assemblages 🗸 🗸 📃	
	Don't color fields		
	🖂 Bounds	1 pt — 🗸 📃 🗌 Smooth lines	
	🗹 Labels	22 pt 🗧 🖪 🛛	
<	Label type	Shortened names	
	🗹 Legend	12 pt 🔹 📕 🖪 I	
	X position 7.15 🖨	Y position 7 🚖	
	ОК	Apply Cancel Reset	

the "Shortened names" option is chosen to simplify the assemblage labels. The legend lists each assemblage as it appears on the plot and defines each abbreviation.

8.1.3 Axis Variables

A 2D diagram's axes by default are labeled in terms of reaction progress, which has meaning only in terms of how the calculation is set up. Use the **Format** \rightarrow **Axis Range and Variables...** dialog to control the variables appearing on the *x* and *y* axes, their units where applicable, and to set custom ranges and tick increments. For more information, see **Progress variables** in this guide.

8.2 Cross-section Plot configuration

You can plot one or more horizontal or vertical cross-sections through the calculated 2D diagram. Horizontal sections represent progress along the scanning paths, while vertical sections represent progress across the scanning paths.

Using P2plot 199

Choose **Plot** → **Cross-section Plot...** to configure a cross-section plot. You can alter the configuration by interacting with the graphical aspects of the plot, such as any data line, data label, axis, tick mark, label, or grid line. A **right-click** on an aspect of the plot displays a menu showing the options available. **Double-click** on an aspect to invoke the **Cross-section Plot Configuration** dialog. Dragging an inner or outermost axis tick mark, number, or grid line will shift or scale, respectively, the axis range, (see **Using Gtplot** in the **GWB Essentials Guide**).

The **X** Axis tab lets you specify whether a horizontal or vertical cross-section is shown. The default *x*-axis setting is reaction progress in the *x* direction (a horizontal section). Use the **Orientation** pulldown to control the orientation of the cross-section.

The **X** Axis tab also lets you select the variable to appear on the *x* axis. Most commonly you would choose the variable or variables representing reaction progress (see **Progress variables** in this guide), but a cross-section plot, like an XY plot in **Gtplot**, can plot any variable on the *x* axis. For this reason, progress variables are not listed separately from the larger set of variables. Use **Variable type** to control the type of variables to appear along the *x* axis. Variable type options are:

- Chemical parameters such as temperature, pH, and mass solution
- Physical parameters such as fluid density, porosity, and fluid velocity
- Reactant properties such as net reaction progress and reaction rates
- Components in the fluid, minerals, sorbate, and the bulk system (fluid plus sorbate and rock)
- Component Kd's of the various components that may be sorbed onto mineral surfaces
- Sorbed fractions of the various components that may be sorbed onto mineral surfaces
- Surface parameters such as charge density, potential, and sorbing surface area
- Species to plot either the concentration, activity, or activity coefficient of one or more aqueous species
- Minerals to represent the masses or volumes of minerals and end members over the reaction path

- **Mineral Saturation** to plot the saturation indices (*Q/K*) of the fluid with respect to one or more minerals, as well as any solid solutions considered
- Gas partial pressure and Gas fugacity of one or more gases in the fluid
- **Elemental Composition** of the fluid, the rock, the sorbate (i.e., surface complexes), or the system (fluid plus sorbate and rock)
- Isotopic composition of the bulk fluid, rock, sorbate, and system, as well as individual species, for active isotope systems

The selection of a variable type displays a list of possible variables. Click on a variable you wish to select. Use the following to specify the way the variables are plotted:

- Variable type to control the type of variables to appear along the plot's axis
- **Filter** to list, for species or mineral saturation plots, the set of just those that contain a given basis species
- Auto-scale to set the data range for the axis to span the data to be plotted
- Minimum, Maximum, and Tick increment to set the data range for the axis
- **Reverse axis** to reverse the sense of the axis
- **Units** to select alternative units, if any, for the axis
- **As** to plot values as elemental equivalents, or as protonated or deprotonated species equivalents
- **Type** to set the axis to a linear, log, or delta scale. A delta scale shows change in a variable's value from the initial point in any particular step
- First, Previous, Next, and Last to cycle through the variable choices

Cross-section Plot Configuration — Select X-axis Variable			\sim Cross-section Plot Configuration — Select Y-axis Variable(s) \times					
X Axis Y Axis Ste	р			X Axis Y Axis	Step			
Variable type Chem	ical parameters		~	Variable type	Species concentration		~	
Filter			\sim	Filter	As04		~

Rxn progress (x) Rxn progress (y) Temperature Mass H2O Mass solution Uissoned solids FH f D2(s) Eh pe Ionic strength Chlorinity m Cl- Activity of H2O			First Previous Next Last Select all	As04 H2As04- H3As04 HAs04- >(w)FeH2As0 >(w)FeHAs0 >(w)FeHAs0 >(w)FeOHAs	4. 04		First Previous Next Last Select all	
Auto-scale F	Reverse axis			Auto-scale	e 🔲 Reverse axis			
Minimum	2	÷	\sim	Minimum	0	÷	mmol/kg ~	
Maximum	12	÷		Maximum	1.1e-5	-	as Species 🛛 🗸 🗸	
Tick increment	1	🗧 linear	~	Tick increment	nt 5e-6	*	linear ~	
ОК	Apply	Cancel	Reset		OK Apply		Cancel Reset	

The **Y Axis** tab lets you select the variables to plot on the *y* axis and specify the way they are plotted. Choose a **Variable type** and variable just as you do on the *x* axis. Use the **Filter** menu to set, for species or mineral saturation plots, a basis species to consider. In a typical calculation, so many dissolved species are considered, and saturation states are determined for so many minerals, that the data fit poorly on a single plot. For this reason, **P2plot** can group species and minerals into sets of just those that contain a given basis species. You can choose to plot, for example, the species containing Na⁺, or the saturation indices of minerals containing Al⁺⁺⁺. Alternatively, you may choose to consider all species and minerals.

The selection of a variable type displays a list of possible variables. Click on a variable you wish to select. Use **Ctrl+click** to select multiple variables. Use **Shift+click** to select a range of variables.

The **Step** tab lets you select the position in the diagram for which data should be rendered. If you are plotting a horizontal section (a scanning path), the step indicates reaction progress along the vertical direction (the staging path). If you are plotting a vertical section (the staging path, or parallel sections), the step indicates progress along the horizontal direction (the scanning path).

Depending on how the calculation is configured, one or more descriptive progress variables may be available. Use the **Progress variable** pulldown to choose from the available options. The progress variable aids in step selection and is used to label cross-section plots.

Use the **First**, **Previous**, **Next**, and **Last** buttons to cycle the plot through the steps.

You can choose from the **Y Axis** or **Step** tab to display several values from a single step, or one value from several steps.

8.3 Plot types

Use the **Plot** menu to choose between the 2D Diagram View and the Cross-section Plots. Each selection invokes a dialog box specific to the type of plot in question (see **Using Gtplot** in the *GWB**Essentials**Guide***).**

8.4 Editing plot appearance

P2plot allows you to interactively modify many aspects of the diagram. The details of using active items, aspect menus, and dialogs to edit the plot appearance are given in the **Using Gtplot** section of the **GWB Essentials Guide**.

8.5 Reaction traces

P2plot can overlay onto a 2D diagram the trace of a reaction path (a ".gtp file") calculated with the **React** program.

To read a .gtp file into **P2plot**, select **File** \rightarrow **Open** \rightarrow **Reaction Trace...** Clear a trace from a diagram on the **Open** \rightarrow **Reaction Trace...** dialog, with the OFF button. The **Reaction Traces** section of the **Using Act2** chapter in the *GWB Essentials Guide* gives details on plotting traces of **React** simulations. Unlike in **Act2** and **Tact**, you can currently load only one trace into **P2plot**.

8.5 Scatter data

P2plot can overlay the data in a **GSS** data sheet (a .gss file) as "scatter data" on a plot of the results of a **Phase2** calculation. The program can add scatter data to any of the 2D diagrams it makes, as well as the cross-section plots. To coordinate the plotting of sample dates and times in the **GSS** data sheet on a cross-section plot, set an explicit starting date and time in **Phase2**.

To read a .gss file into **P2plot**, select **File** \rightarrow **Open** \rightarrow **Scatter Data...** Clear scatter data from a diagram on the **Open** \rightarrow **Scatter Data...** dialog, with the **OFF** button. The **Scatter data** section of the **Using Gtplot** chapter in the *GWB Essentials Guide* gives details on plotting scatter data from .gss files.

In GWB releases 7.0 and earlier, the program took scatter data from a specially formatted text file, rather than a .gss data sheet. Legacy scatter files are still supported, and are described in the **Scatter Data** chapter of the **GWB Reference Manual**.

8.6 Loading and saving plot configuration

Upon finishing, **P2plot** writes into the user's working directory a file, "p2plot_conf.p2c", containing the configuration of the current plots. When the program starts again in the same directory, it reads the file and assumes the same configurations.

Choosing File → Reset Configuration or the reset option from the command line (see P2plot command line) returns the configuration for each plot type to its default state.

You can also save plot settings in ".p2c" configuration files. To do so, select **File** \rightarrow **Save As...** You can then specify that file as the configuration for a later **P2plot** run from the command line (the -c flag; see **P2plot command line**) or read it into **P2plot** by selecting **File** \rightarrow **Open** \rightarrow **Configuration...**

Exiting the program by choosing **File** → **Abort (No Save)** causes an immediate exit from the program; the plot configuration is lost.

8.7 Exporting the plot

P2plot makes it convenient to use the plots you create in articles, reports, presentations, and databases. You can copy the current plot to the clipboard and then paste it into a variety of applications, in a format meaningful to the application.

To copy a plot, use **Edit** \rightarrow **Copy** or **Ctrl+C**. If you paste the plot into MS PowerPoint, it will appear as an EMF (an MS Enhanced Metafile) graphic object. Pasting into Adobe Illustrator places a native AI graphic.

If you paste the plot into MS Excel or a text editor, such as Notepad or MS Word, the numerical values of the data points that make up the lines on the plot will appear in spreadsheet format.

You can control the format in which the plot is copied to the clipboard by selecting **Edit** \rightarrow **Copy As**. You can choose to copy the plot as an AI object, an EMF object, or a bitmap, or to copy the data points in the plot as tab delimited or space delimited text. Use the tab delimited option to paste the data into a spreadsheet program like MS Excel. For examining the data in a text file created with an editor like Notepad or MS Word, copying from **P2plot** using the space delimited option and then pasting into the editor writes a nicely aligned table.

8.8 P2plot command line

To run **P2plot**, click on the **P2plot** icon on the GWB dashboard, or open a ".p2p" or ".p2c" file. The program can also be initiated from the Windows command prompt by typing p2plot.exe. Starting the program in this way allows you to make use of the command line arguments described below.

P2plot accepts a number of arguments from the command line. For example, the command

```
p2plot -i Phase2_plot1.p2p -c Config1.p2c
```

causes **P2plot** to read as input the file "Phase2_plot1.p2p", and to use the plot configuration stored in "Config1.p2c".

The following options are available from the command line:

-i <input_data></input_data>	Set the "Phase2_plot.p2p" dataset, produced by a Phase2 run, which contains the data to be plotted. The program, by default, looks for file Phase2_plot.p2p in the user's working directory.
-c <config_file></config_file>	Set the configuration file to be read at startup. By default, the program reads the file p2plot_conf.p2c if it exists in the working directory.
-trace <trace_file></trace_file>	Set the "React_plot.gtp" dataset, produced by a React run, to plot as a reaction trace. By default, P2plot does not plot reaction traces.

-scat <scatter_file></scatter_file>	Take scatter data from the named dataset. By default, P2plot does not plot scatter data.
-graph <plot_type></plot_type>	Set the type of plot displayed at startup. By default, it is set from the configuration file. Choose from: 2d and cross-section.
-reset	Set the default configuration at startup; do not read p2plot_conf.p2c.

The following literature references, from the many hundreds that have been published, provide a starting point for further reading on various aspects of geochemical modeling and its applications. Additional references are available in the *GWB Essentials Guide* and the *GWB Reactive Transport Modeling Guide*.
